29,631 of 1904, 11,033 of 1906, 11,346 of 1906, and 11,884 of 1906. It is applicable wholly or in part to that type of film pack in which the unexposed films lie in a pile at the front of the case, each film being separate and independent from the other, and transferred from front to back of the case after exposure; it is also applicable wholly or in part to the type of film pack in which the unexposed films lie in the folds of a pleated strip, by which they may be moved from front to back, or back to front of the case, according to the arrangement of the parts. It will be understood that the invention relates entirely to the type of packages of films which are sealed up by the manufacturer for sale in their wrappers or cases, and that the said cases are placed bodily, with their sensitive contents intact,

FIG. 1.

into the camera or an adaptor for use. Whilst in this position the films may receive the photographic impression by exposure, then have their order or position changed by the operator, in rapid sequence; and after all have been exposed, the package, still complete in its original wrapper or case, is removed from the camera. The whole operations are performed in broad daylight, without recourse to a dark room.

The films A are contained in a light-tight enclosing case or wrapper B having an exposure opening *b* cut in the front side thereof, and are superimposed in a pile therein in one of two positions, being transferred or moved from the first to the second position as they are exposed, by means of pull tabs *a* attached to the films, or by means of a pleated strip of paper. The outer case or light-excluding wrapper B may be made of paper, cardboard, thin sheet metal, or other like material that can be readily bent and will retain its shape thereafter.

The films A, which may be mounted in the case B either to be drawn from the front to the back or from the back to the front, may be mounted in any convenient way upon an opaque backing.

In some of the earlier film packs, including that now in general use, the user places the package in the camera in daylight and unseals it or uncovers the films when in that position. The package has to remain there until all the films are exposed or changed to the back, whereupon the pack becomes automatically resealed and can then be removed from the camera in daylight.

Thus each picture cannot be separately focussed upon the ground glass of the camera, and the only way to secure that desideratum is to use an adaptor, which is a dark slide that receives and completely encloses the film pack on all sides except an opening in the front, this opening being closed by a sliding shutter or equivalent device. By withdrawing this shutter when the adaptor and package are in the camera the front film is exposed, and after replacing the covering shutter the whole adaptor and film pack complete may together be removed from the camera and the picture focussed on the ground glass.

In this invention the necessity for an adaptor with covering shutter is dispensed with by making the latter an integral part of the film pack itself, which can be done in various ways.

In addition to the tabbed films and tabbed covering shutters I may add tabbed colour filters for orthochromatic or for tri-chromatic work, consisting of sheets of gelatine, collodion, or other like transparent media, dyed with suitable transparent colours, and each sheet filter being provided with its own manipulating tab. By interspersing these filters with films in sets for tri-chromatic negatives (such as yellow, red, and blue, for example), the respective exposures can be made in rapid sequence without removing the pack from the camera and without need of the cumbrous sliding backs or holders containing glass colour screens which have to be moved after each exposure or the

FIG. 2.

other alternative and equally inconvenient method of changeable colour screens on the lens with corresponding changing of plates and plate-holders.

The screen may be of gelatine, collodion, or the like ruled with fine close lines or bands of colour arranged thus—red, blue, yellow, red, blue, yellow, according to the well-known process of Professor Joly, or of the Lumière type of colour film, with a layer of fine coloured starch-grained particles which split up and filter the light passing through before it reaches the sensitive surface, or it may consist of a number of layers which go to build up a composite film being prepared according to the process of Dr. Smith, in which each sensitive layer is stained to filter or be affected by a different colour of light and the respective layers are isolated from each other by a transparent stripping media such as india-rubber, collodion or the like, to enable them to be split apart afterwards, but the whole forms a single sheet, which is attached to the opaque tabbed backing.

Such colour screens can, if preferred, be attached to the films or to the backings so as to cover the films and pull with them, but by making them to work quite independently of the films or backings, the thickened stiff edge that interferes with freedom of turning over when transferring is avoided, as happens when all are joined together and operated as one piece. John Edward Thornton, Altrincham, Chester.

## New Trade Names.

FIGARO.—No. 293,740. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Pinchin, Johnson, and Co., Ltd., 23, Billiter Street, London, E.C., varnish, colour, and paint manufacturers. June 13, 1907.

THE "PHOTO-MINIATURE" FOR MARCH.—This issue of our useful little contemporary is just to hand, and deals with the choice and use of photographic lenses. The five aberrations are dealt with in a simple manner, and we then have a brief description of the different types and lens constants. The English publishers are Dawson and Ward, 6, Farringdon Avenue, E.C.

J. GUNSTON, LIMITED (photographers, Bradford).—A debenture, dated June 24, 1907, to secure £200, charged on the company's undertaking and property, including uncalled capital, has been registered. Holders—J. W. Booth, Keighley, York; J. E. Longdin, Park Crescent, Bradford; and T. O'Keeffe, Wellington Crescent, Ecclehill, Bradford.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Focussing.

The dark corners of the ground glass (writes Mr. W. Easton in "Photography") are veritable "booby-traps." It is so difficult to see the picture on them, that one gets to ignore what is there. But, dark and obscure as they are on the focussing screen, they will be as bright, and the objects there may be as conspicuous in the print, as those in the centre of the image, and if we ignore them we may find that they have had their revenge by spoiling our picture, either by including something that ought to be left out, or by showing something fuzzy that ought to be sharp. Having noted the position of the ground glass for these two objects, either by observing the position of the milled head of the focussing screw, or, better still, the actual position of the sliding part of the camera on the fixed baseboard, the back is to be set as nearly as possible midway between the two positions, and should not afterwards be removed therefrom until the exposure is made. Then the largest stop that there is any prospect of being able to use to get both those objects sharp at the same time is to be put in and tried. If they are sharp, that is the stop to use; if they are not, then stop by stop must be tried, examining the image carefully after each change, until one is found that gives them both with the definition that is required. That is, then, the stop to employ.

### Simplified Factorial Development.

Mr. Alfred Watkins, writing in "The Photographic News," with reference to the paragraph on page 525 in our last issue, says:—"Anyone can find the method fully expounded on page 93 of the third edition of the 'Watkins' Manual,' published early in 1906, the opening paragraph being as follows: 'Simplifying Calculation.—The total time of development can more easily be calculated if such a developer be used that its factor divides evenly into 60, the product being then used to divide the seconds appearance in order to obtain the number of minutes to develop.' A full explanation of the method follows. Of course, I have no doubt that Mr. McGregor hit upon this simplification quite independently, and no doubt others have done the same, for no one could go on long using, for instance, a developer with a factor of 10, multiplying the seconds appearing by 10, and dividing by 60 to get the minutes to develop, without seeing that it is the same thing to divide in the first place by 6. But, useful as this is as an adjunct, it can never take a place as a universal method. It is only applicable to such factors as will divide evenly into 60. Factors such as 7, 8, 9, 11, 13, and 14, all those between 15 and 20, between 20 and 30, and between 30 and 60 cannot be calculated by this simplified method, and this limitation cuts out quite one half the pyro-soda developers. Besides, the method tends to a want of elasticity in development. I, like many other workers, use a higher factor for a negative for carbon than I should for enlarging, and prefer to have no limitation in my choice of a suitable factor for my want. For these reasons I find the small mechanical calculator the most suitable, as I then use neither pencil nor mental arithmetic. I am sorry to see the word 'factor' applied to these new dividing numbers, and I must point out that this may lead to endless confusion and inconvenience. Already there has been some little confusion between the development factor of Messrs. Hurter and Driffield and the entirely distinct factor in the factorial method, and technical writers designate the latter the Watkins' factor for distinction. Editors and other writers referring to developers now often speak of them as 'high factor' or 'low factor' developers, as these terms conveniently describe their attributes. But with the dividing numbers these proportions are reversed—high becomes low and low becomes high. I think the most convenient designation for them would be 'divisors.'"

### Tank Development.

Glycin is preferred by many for this method (writes Mr. G. E. C. Morris in "The Amateur Photographer"), but it is an expensive salt and a very slow developer. Nevertheless the results obtained by its use are excellent. I find the use of bromide with rodinal is not actually necessary when working with slow plates, but with orthochromatic

plates and ordinary plates of high speed several drops of 10 per cent solution is advisable. With pyro and all other developers it is necessary, but should be used with discretion to avoid harsh contrast, especially with pyro. I am sure that this method of development will prove a tremendous blessing to those who have no aptitude poring over the developing dish on a fine day. It tends to produce technically better negatives, and with colour-sensitive plates the fact that they are developing in complete darkness should at once recommend itself. Everyone has his own favourite developer, and, far as I know, tank development is applicable to most. There is reason why each worker should not experiment for himself with his own particular formula, bearing in mind that the chief point is to mix the solution from three to four times its normal strength, give plenty of time for it to act.

### CATALOGUES AND TRADE NOTICES.

Voigtländer and Sohn, of 12, Charterhouse Street, E.C., have sent us a copy of their latest price-list, a beautifully printed and illustrated work of 130 pages. The first half is confined to "Hens on Lenses," by Dr. Hans Harting, F.R.P.S. Here will be found some useful hints not only as to the particular lenses, but also general work, the subjects dealt with being depth of focus, aperture, colour filters, telephotography, etc.

The Tella Camera Company have just issued an illustrated, up-to-date price-list of all kinds of photographic apparatus and accessories, which may be obtained at their new establishment, 68, E. Holborn, London, W.C. Particulars and illustrations of the latest models of cameras, lenses, etc., are given, and the selection by large and varied, should meet the requirements of all classes of photographers. This firm also makes a special feature of second-hand goods, of which they have a large stock at much below original cost, and monthly catalogues relating to these will be sent to any of our readers post free on application. Old apparatus also taken in part payment for new, and goods may be purchased on the extended payment system extending over periods varying according to the amount of the purchase.

## Dew Apparatus, &c.

The "Sanderson" Rubber Tripod Shoe. Made by the Altrincham Rubber Company, Altrincham.

This useful little device is constructed of stout white rubber an enlarged finger-stall, and can be easily slipped on and off tripod end. Being corrugated at the end, it grips a polished face well, and will thus prevent that annoying slip to which the legs are so prone. They are sold in boxes of three, in three sizes: 1s. 6d., 2s., and 2s. 6d. respectively.

A NEW SHUTTER.—Remarkable interest has been excited, the "Photo-Miniature," by the announcement of the multi-speed shutter, a new lens shutter introduced by the Multi-speed Shutter Company of New York. This shutter is guaranteed to give accurate exposures from slow, instantaneous, bulb, and time exposure high instantaneous speeds, ranging from 1-200th to 1-2,000th of a second, with three times as much illumination at the highest speed as is obtained with a focal-plane shutter. It is even claimed the multi-speed shutter will give exposures of 1-4,000th and 1-6,000th of a second.

NOTTINGHAM CAMERA CLUB.—At the Mechanics' Institution a meeting was held on July 9 of those members of the Nottingham Camera Club who had subscribed to a purse of gold for Mr. Arthur Black presented as a slight mark of their appreciation of his work for the club, more particularly in connection with the last six annual exhibitions. The presentation was made by Mr. Thomas Wright (president), and, among others, Mr. H. Roberts (chairman) and S. W. B. Vines (hon. secretary) spoke. Mr. Black expressed thanks and briefly foreshadowed the future work of the club.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

SAURDAY, JULY 20.

ed Stereoscopic Society. Outing to Chislehurst.  
th London Photographic Society. Outing to Zoological Gardens.  
t London Photographic Society. Outing to Staines Moor.  
th Middlesex Photographic Society. Outing to Lemsford Mill and Brockett Park.  
th London Photographic Society. Outing on River Thames.  
ntol Photographic Club. Outing to Brisington and St. Anne's.  
ds Camera Club. Excursion to Hebdon Bridge.  
th Suburban Photographic Society. "The Pilgrim's Way."  
th Park and District Photographic Society. Joint Outing with the North  
Middlesex Photographic Society to Lemsford Mill and Brockett Park.  
i Photographic Society. Outing to Thornton Abbey.

MONDAY, JULY 22.

ford Photographic Society. Ramble to Kirkstall Abbey.

nction of Members' Photographic Goods.  
rton Camera Club. Evening at Bidston.

TUESDAY, JULY 23.

dney Photographic Society. "Oil Printing." H. W. Lane.  
chester Amateur Photographic Society. "Bromide Paper." Dr. A. T.  
Lakin. "Velox." J. J. Phelps.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—At the last meeting of the  
ve society the new Leto Pigment paper was demonstrated by the  
n. secretary, Mr. Gideon Clark. The paper is sent out coated with  
thin layer of gum pigment, at present in black only, and is  
sitised with ammonium chromate and methylated spirit. With  
s quick-drying sensitiser it is possible to produce a finished print  
thin forty minutes from time of sensitising. Mr. Clark remarked  
at the attractive feature of this new pigment paper was the extra-  
nary scope it allowed for personal control during development,  
ich can be done with hot water in a similar manner to the  
inary carbon process, the first print being far less delicate and not  
liable to extreme solubility as in the ordinary gum bichromate  
cess. The finished prints have an appearance similar to a fine  
mezzotint engraving. Several fine examples in landscape, archi-  
ture, and portrait work in this process were shown, the latter  
ng specially admired.

## Commercial & Legal Intelligence.

**PHOTOGRAPHER FINED.**—William Dawson, photographer's can-  
ser, residing at 29, Harbour Street, was charged at Nairn Police  
rt last week with having been found drunk and incapable.  
used pleaded guilty, and was fined 5s., or three days' imprison-  
nt.

**ALLEGED WRONGFUL DISMISSAL.**—At the Clerkenwell County  
rt on July 11 the action was mentioned of Robert Melville,  
ountant and foreign correspondent, Crayford Road, Holloway,  
Messrs. Underwood and Underwood, stereoscopic publishers, 105,  
gh Holborn. In this case, heard before the judge and a jury on  
y 10, plaintiff claimed £72 11s. as damages for alleged wrongful  
missal. Plaintiff, as book-keeper and foreign correspondent in  
endants' employ, was receiving £240 per year. He declined to  
e a reduction, and tendered his services on the old basis. The  
r was declined, so plaintiff left. He claimed that he was  
titled to three months' notice. The jury found that, having  
ard to defendants' position, one month's notice would be a  
sonable one. Upon the judge's direction, they awarded £20 for  
month's salary in lieu of notice, and £4 15s. as money due to  
n. Mr. Thomas, for defendants, said his clients had paid into  
rt £25, and as the damages awarded by the jury were below  
t sum, he asked for judgment for plaintiff. The entering of  
gment was postponed. Mr. Ward, counsel for plaintiff, now  
mitted that his client was entitled to three days' salary above  
at the jury had allowed. He worked on two days after his week

ended, and tendered himself for work on the Monday. That being  
so, he asked that judgment be entered for plaintiff for £26 19s.  
Mr. Thomas said the entering of judgment was postponed for the  
question to be dealt with as to whether defendants, having paid  
more than the amount awarded into court, were entitled to costs.  
He pointed out that in the particulars the day of the alleged  
wrongful dismissal was set down as Friday. The judge held that  
the verdict must be entered for defendants. Mr. Ward applied for  
a new trial on the grounds that the jury's verdict was against the  
weight of evidence; that his Honour did not sufficiently direct the  
jury as to the measure of damages; and that the damages were  
inadequate. The application was refused.

## News and Notes.

**THE STEREOSCOPIC SOCIETY** is now engaged in distributing the  
year's slides among the members. During the past twelve months  
275 slides and four stereoscopes have been allotted to the children's  
ward of the Royal Infirmary, Aberdeen, and 120 slides and two  
stereoscopes to a local cottage hospital. This is the fifteenth year of  
the society's existence. There is a vacancy for one member; entrance  
fee is 1s. 6d., and annual subscription 2s. Application should be  
made to the hon. secretary, B. Diveri, B.A., Huntly, N.B., who will  
be pleased to give further particulars.

**CELLULOID DANGERS.**—Mr. Herbert Gladstone, the Home Secre-  
tary, in reply to a question put to him, foreshadowed the possi-  
bility of Government legislation on the subject of the dangers of  
fire arising from the use of celluloid articles. On being asked  
whether his attention had been drawn to the danger from fire caused  
by articles made of celluloid, xylonite, and other similar sub-  
stances, which are highly inflammable when in proximity to arti-  
ficial light, and whether he would consider the desirability of grant-  
ing powers to local authorities with respect to the storage and sale  
of such articles, Mr. Gladstone replied that this question had been  
under consideration for some time, and that he had communicated  
with the London County Council on the subject of legislation.

**THE ILLINGWORTH ZIGAS COMPETITION.**—The competition for pro-  
fessional work on the lately introduced gaslight paper manufactured  
by Messrs. Thomas Illingworth and Co., of Willesden Junction,  
under the name of "Zigas," was brought to a conclusion at the end  
of last month. The offer of £40 in money prizes for the best work  
on "Zigas" paper had evidently proved an incentive to a great  
many professional photographers of the middle class to take part  
in the competition, but it was a matter for some regret that there  
was not a larger proportion of work which might justly be classed  
with that of the very highest order. In the absence of much com-  
petition of this kind the judge, Mr. G. E. Brown, editor of the  
BRITISH JOURNAL OF PHOTOGRAPHY, did not feel justified in making  
the highest award, but the following are the names of those who  
obtained prizes:—First prize (withheld). Second prize: George  
Henderson, Hebburn-on-Tyne. Third prize: Oscar Owens, South-  
sea. Cash prizes of £1: J. Moffat, Edinburgh; H. Shelton, Not-  
tingham; Sidney Hicks, Dublin; S. H. Greenway, Northampton;  
R. Goodyer, Bognor, Sussex. Many of the prints showed the high  
technical excellence which can be attained by means of the "Zigas"  
brand of paper, whilst many others, on the other hand, demon-  
strated that the users had not paid sufficient attention to the simple  
yet important items in which a paper of the gaslight variety is dis-  
tinguished from a bromide. That the rapidity of working is often  
of the greatest advantage every photographer has reason to know,  
and he should also keep before him the fact that care and observa-  
tion only are required to combine such speed in working with a  
high quality in the finished productions.

**THE "CAMERA HOUSE JOURNAL,"** the business bulletin of Messrs.  
W. Butcher and Sons, Limited, contains in its latest issue special  
particulars relating to their "Cameo" and "Carbine" cameras, and  
also to their "Ralli" series of focal-planes. They are issuing show-  
cards for the use of dealers to advertise the "Clincher" and "Pilot"  
magazine cameras, which are fitted with a revolving price-card to  
allow of the price of the special model exhibited being shown.

Messrs. Butcher also state that their warehouse will be closed on July 20, the day of their annual outing.

**HERIOT HOSPITAL SCHOOL CAMERA CLUB.**—An exhibition of photographs was held on the 10th inst. in connection with the Heriot School Camera Club at the new art rooms of the school, Lauriston Place, Edinburgh. Each section was strongly represented, and the quality of the work was very good indeed. The efforts of some of the boys would compare favourably with many exhibits of more pretentious societies. Mr. T. A. Clark, the president, gave an account of the work and progress of the club, and Dr. Lowe, headmaster, proposed a hearty vote of thanks to Mr. Clark. The prize-winners were Eric Allan Rendall, the club bowl for former pupils; Stirling Baird, the MacGregor bowl; J. Whitehead, J. C. Brown, J. H. Donaldson, J. Underwood, F. J. Walls, and W. H. Ferney.

A SOMEWHAT serious fire occurred at the premises of Mr. W. Illingworth, photographer, of Abingdon Street, Northampton, on the 8th inst. It began in the enlargement-room, and though the alarm was quickly given and prompt assistance obtained, some hundreds of pounds' damage was done. It is stated that Mr. Illingworth has lost about a thousand specimen photographs and a case of plates.

AT THE MEETING of the London and Provincial Photographic Association on the 11th inst. Mr. T. E. Freshwater (chairman) moved a vote of condolence with the family of the late Mr. A. L. Henderson, father of the association. Mr. R. Child Bayley then read a paper, and showed examples of the Autochrome plates of Lumière, which were much admired for the purity of the blacks and whites and the truth of the greens and greys. Mr. Sinclair thought the association fortunate in being the first to see these results, the first in this country; the ease of working was quite sufficient to make one want to use it. Mr. Haddon made comparisons with the Joly process, that being in lines, this in grains, that having a separate screen, this being coated under the emulsion, and then being exposed through the back. He also suggested the use of glass, powdered instead of stained starch grains, as being more permanent. Several members doubted the possibility of getting suitable glass.

**THE KODAK £400 COMPETITION.**—At the Kodak Gallery, 40, Strand, a collection of about 60 enlargements, selected from more than 28,000 sent into the above competition, are now on view. In every case with the enlargement is shown a print from the original negative, and this forms a striking lesson in the capabilities of the cameras, of the paper, and of enlarging. Amongst the prize-winners are Steichen, Stieglitz, Harold Baker, Dan Dunlop, Mrs. Barton, and other well-known names. The show is well worth a visit.

**CANVASSING FRAUDS.**—At North London Police Court on Monday, William Jones, 44, canvasser, with no fixed abode, was charged, on remand, with being a suspected person found upon enclosed premises with the supposed object of committing a felony. He went to the house (at Aberdeen Park) of Mr. James W. Sharp, a prominent member of the old School Board for London, and walked uninvited into the kitchen. When one of the maidservants (Annie Deamer) found him there she asked him, "Who are you, and what do you want?" He uttered something and she fled. But Mrs. Sharp sent for the police, and the prisoner was found in a public-house near by. He then said he was canvassing for a photographer, and had on him some specimens. He added that he knocked at the door of the kitchen, and then turned the handle and walked in, expecting to find the servants there; and he ran away because he did not want to get into any bother. Detective Hall now proved three previous convictions against the prisoner—three months, one month, and 21 days—for stealing money entrusted to him by servants and others for photographs. Mr. Biron sent the prisoner to gaol for three months' hard labour.

**SAFE FLASHLIGHT.**—The "Photographische Rundschau" states that a perfectly safe and non-explosive flashlight mixture can be obtained by mixing equal parts of magnesium powder and anhydrous chrome alum. This burns rapidly, and gives a good light, whilst a slower burning mixture is obtained by mixing the above with one-fifth its weight of infusorial earth or powdered glass. As flashlight mixtures can be obtained at very reasonable prices now, it is hardly worth while mixing them, as a great deal of their efficacy depends upon intimate mixing and freedom of the magnesium from oxidation, to which, when it is kept in the ordinary way, it is very liable.

## Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### STAND DEVELOPMENT.

To the Editors.

Gentlemen,—I have read with great interest the very instructive articles in the last two numbers of the "B.J." on "tank" and "stand" development. I have recently entirely changed my tactics in this direction, with results which have led me to decide that henceforth, except occasionally, I am not likely to use any other method. I have used glycin, as recommended, for the purpose, but I see no reason why one should not be very successful with other developers, each photographer, perhaps, with his own favourite developer selected for its suitability to the kind of plate he may be using.

My greatest difficulty has been in selecting a suitable tank. There seem to be only very few on the market, and those only for one or at most two sizes, of plate. It is largely with this practical object that I am writing, and should be much obliged to Mr. Harris if he would kindly indicate more nearly the kind of dipping-bath which he has used. I have dipping-baths for the nitrate of silver which I used when I practised the wet collodion process. These, of course, will only take one plate at a time. It would almost seem that those of Mr. Harris must take more to enable him to develop such a large number of plates in so short a time. It seems to be in other respects a very convenient form of tank. I obtained my own tank from Germany, made to take two sizes of plate, and means of an adapter I am able to develop two other of my size of it, but plates of one size only at a time. I work with several different sizes from 9cm. by 12cm., continued up to 7½ in. by 6

this latter and one other being sizes not in the market. Mr. Harris' article has led me to think of an arrangement by which any one of all of these may be worked at the same time; otherwise it is necessary to procure several tanks of different sizes.

As I should think now, judging from its merits and the way in which these are being made known, that this method of development will begin to be largely used, it might be worth the while for some one of the many enterprising firms to take up the matter thoroughly and produce at moderate cost a tank more independent of the size of plate which photographers might find more generally useful. I will show one idea that has come into my mind which might be superseded by something better or improved upon, taking the old nitrate dipping-bath as the germ of the idea:—

The bath should be made not to take one dipper only, but several, say a dozen, one beyond the other, as I have represented them in the accompanying figure. It should be made with grooves like a plate box. The grooves should not be upright, but sloping downwards with the angle of the dipper in the nitrate dipping-bath. The dippers should be made as broad as the tank and so as to fit into the grooves like plates. The dippers might be in one solid piece forming a kind of framework, as in my sketch. That might allow free circulation of the developer. The plates, whether large or small, would lie comfortably on the flat dippers, and any one of them could be conveniently withdrawn, examined, and replaced without disturbing the others. With such an arrangement up to my largest size plate I could use any of my sizes, whether

ental or English, or my more special sizes—7½ by 6 and 5½ by 4 have seen lately, perhaps in the "B.J.," something of this kind noticed, but on inquiry I found it to be for the English plate size only. It should be more generally useful, and to many photographers to buy should be moderate in price. At the same time I am wishing to find a tank of this kind for my fixing.—  
etc.,  
anne.  
W. WASHAM.

## Answers to Correspondents.

*matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*respondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., Wellington Street, Strand, London, W.C.*

*for the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the application.*

### PHOTOGRAPHS REGISTERED:—

Ball, 10, Bridge Street, Blaydon-on-Tyne. *Photograph of the Blaydon Hall Schools Boys' Football Club.*

Bloss, Gainsborough House, Cirencester. *Photograph of Right Hon. Austin Chamberlain.*

Haigh, 293, Eccles New Road, Weaste, Manchester. *Photograph of the grave of the Lady of Lourdes in the Grotto at the Monastery, Pantasaph.*

Stock, 7, Castle Street, Thetford, Norfolk. *Photograph of Stone Coffin unearthed at Thetford Gas Works.*

**EUSTACE.**—We think you have been hardly treated, and would advise you to pay 7s. 6d. into court and dispute the matter sum.

**HER.**—Probably the negative was too thin to give density. You should have used a chloro-bromide or gaslight plate, and developed early, then intensified. Your formula is about correct, though we should reduce the bromide to one-fourth of the quantity.

**PHOSPHORESCENT PAPER.**—Will you please tell me (1) where I can purchase phosphorescent paper, or (2) the mixture for sensitising the same?—**COPYIST.**

So far as we are aware, phosphorescent paper is not a commercial article. 2. Phosphorescent paint is either calcium or strontium sulphides suspended in gum-water.

**ON COLLODION PRINTS.**—I have used a certain brand of C.C. paper for some months, and have been very pleased with it, but some prints that have only been done a fortnight, and shown in the shop window, have gone kind of black bronze in shadows, almost like a bloom, dull, and which can be wiped off; but, of course, I do not like prints to go like that. I daresay you will know what I mean, as I have seen C.C. prints go like it before, but never any of our own, as we are so very careful, and we have had large experience in C.C. printing. Do you think using a little saturated solution of washing-soda in first washing-water prevent stains might cause it, by softening the film or coating of paper? I find that has been done lately. Also, do you think using a salt bath before toning advisable? I have used this thinking to harden prints. I may mention that only those prints that have been in platinum bath show any sign of the "bloom"; those that are sepia and that have been toned in

gold only are all right. Do you think that the platinum bath has caused it in any way?—**WYNNE.**

Had you enclosed one or two examples of the trouble we might the better, perhaps, have been able to advise you, as we have never met with such a thing in our own practice. The only suggestion we can offer is that the whole of the hypo has not been washed out of the prints, and, as a consequence, when they become abnormally dry, as they probably do with exposure in the shop window, the hypo crystallises out—thus the "bloom." Some collodion papers are very thick, and absorb a good deal of hypo solution, the last trace of which can only be got rid of by very thorough washing. You might try the effect of rubbing the surface of the prints over with a pledget of cotton wool while in the last washing-water, and then rinse them well under the tap.

**PUZZLED.**—Notwithstanding your statement about extra thorough washing, we can only say that insufficient washing is, so far as we know, the only cause.

**HYDROQUINONE STAIN.**—Can you tell me if lantern slide makers are troubled with yellow slides, the yellowness being caused by insufficient washing before fixing? Will you please tell me if there is a method to remove this yellow stain? Hydroquinone is the developer.—**E. A. M.**

As a rule, those who use hydroquinone wash well, and therefore do not meet with the trouble. It can be removed by applying a weak hypo and ferricyanide reducer, with a tuft of cotton wool to the dry negative, and rinsing frequently, or the slides may be bleached in:

Potassium bichromate .....	15 grs.
Hydrochloric acid .....	5 minims.
Potassium bromide .....	5 grs.
Water .....	1 oz.

then well washed and re-developed with metol or other clean developer.

**D. GREENWAY.**—There is no misprint, and the time is as stated. We presume that the author knew what he was about when he wrote it. The information given is that this method of development is as efficient as, if not more so than, any other. You are not, of course, obliged to adopt it, nor even try it, unless you like.

**S. S. (Tunbridge Wells).**—We are afraid you can do nothing. You did not comply with the request to wire at once, and therefore can make no claim, as the vacancy was filled because your reply was not received in time, and the other party was quite justified in assuming that, as you did not wire, you would not accept.

**ARCHER CLARK.**—Much obliged, but it is not worth while to take any notice of this scribbler's snarls.

**ACID HARDENER.**—(1) In this week's "B.J.," p. 523, there is a very interesting article on sulphide toning. It is suggested that an acid hardener to hypo bath is necessary to avoid blisters. Can you kindly give me a suitable formula for the same? (2) Also would you kindly give me information on the following: After tinting photographic prints, on either P.O.P., C.C., or bromide, they appear very dead, and anything but brilliant in colour. Can I coat same so as to bring up colours with a simple varnish or medium of some kind? The colours used are Winsor and Newton's. Your information will be esteemed a great favour.—**TWO.**

(1) The best hardener would be:

Hypo .....	3 ozs.
Sodium bisulphite lye .....	150 minims.
Chrome alum .....	50 grs.
Water .....	20 ozs.

Dissolve the hypo in the bulk of the water, the sulphite and alum in the remainder, and mix. (2) We do not know whether the colours would stand a varnish, but, if so, the best would be:

Sandarac .....	1 oz.
Benzole .....	4 ozs.
Acetone .....	4 ozs.
Absolute alcohol .....	2 ozs.

It is quite possible that the makers would sell you a medium to mix with the colours which would give a gloss.

**POSTCARD.**—This is a matter entirely for your solicitor. We should say it was libellous.

**R. ROBINSON.**—So far as we are aware, there is no work on the subject, and the ordinary rules of colouring apply. We presume you do not mean coloured prints with a protecting celluloid surface. If so, Jonathan Fallowfield, 146, Charing Cross Road, issues pamphlets descriptive of the same.

**GREEN STAINS.**—Will you kindly tell me the way to remove greenish stains from negatives developed by pyro-ammonia? The stains show after washing.—W. D. BIRD.

We are not quite clear what these green stains are, but if they are red by transmitted, and green by reflected, light, they are the old green fog, of which we do not hear much now. Abney's remedy is to bleach the plate in:

Ferric chloride .....	50 grs.
Potassium bromide .....	30 grs.
Water .....	4 ozs.

Wash and re-develop with ferrous oxalate, which reduces the green fog to a slight black veil. The best remedy is either a 1:1000 solution of potassium permanganate, which dissolves the fog, followed by a bath of acid bisulphite of soda. Or Lüppo-Cramer's bath:

Potassium cyanide .....	25 grs.
Sodium sulphite .....	100 grs.
Water .....	1 oz.

is very effectual; but as this is so poisonous the permanganate is preferable. If our querist merely refers to a greenish image then possibly the familiar thiocarbamide and chrome alum may remove some of the pyro stain. Obviously the best thing to do would be to give up ammonia, which is more prone to cause fog than the fixed alkali, like soda.

**W. E. DIXON.**—From previous knowledge we should advise your customer to at once put the matter in the hands of the police at the place of the firm.

**SENSITOMETRY.**—Please answer the following in the JOURNAL:—1. What are  $\gamma_{\infty}$  and K of Lumière ortho A: developer being standard  $\text{FeO}$ ? 2. What is the strength of standard  $\text{FeO} : \text{N}_{10}$ ,  $\text{N}_{10}$ , or what? 3. Would a developer of 20 cc.  $\text{N}_{10}$   $\text{C}_6\text{H}_4(\text{OH})_{2p}$  and 20 cc.  $\text{N}_{10}$  NaOH have 1.2 or 2.4 times K of  $\text{FeO}$ , same titre? 4. In your test of Eastman ortho plate you give  $\gamma_{\infty}$  as 1.25, K as 0.225. Please state how you arrive at the  $\tau_{71}$  you do?—K. W. M.

1. We have not yet determined these, but will do so. 2. Strength of standard  $\text{FeO}$  is  $\text{N}_{10}$ , i.e., one-tenth of molecular weight of  $\text{FeSO}_4$  in 1,000 cc. in excess of pot. oxalate. Actually prepared by adding 10 cc. of a solution of  $\text{FeSO}_4$  containing 278 grams per litre to normal pot. oxalate, making up to 100 cc. 3. It is best to reckon the solutions of developing agents in terms of molecular weights. 20 cc.  $\text{N}_{10}$   $\text{C}_6\text{H}_4(\text{OH})_{2p}$  + 20 cc.  $\text{N}_{10}$  NaOH gives a developer  $\text{N}_{20}$  to quinol and to alkali, and would have a K 1.2 that of ferrous oxalate on same basis ( $\text{N}_{20}$ ). (It would be more convenient to use the symbol  $\text{M}_{10}$ ,  $\text{M}_{20}$ , etc., referring to molecular weights.) But in presence of 2 mols. NaOH, the K of the quinol developer would be 2.4 that of an equimolecular solution of ferrous oxalate. (See "Theory of Photographic Process," p. 177.) 4. The value for  $\tau_{71}$  is obtained as follows from  $\gamma_{\infty}$  and K:—The equation to development gives

$$1 - l^{-kt} = \frac{\gamma}{\gamma_{\infty}}, \text{ in this case } \frac{1}{1.25} = 800. \text{ From the tables given}$$

in "Phot. Journ.," November, 1904, the value of Kt corresponding to a value .800 for  $1 - l^{-kt}$  is 1.61. As the value of  $k = .225$ , then  $\tau_{71} = \frac{1.61}{.225} = 7.1$  minutes. We should strongly

advise our correspondent to obtain a copy of "Investigations on the Theory of Photographic Processes," by Drs. Sheppard and Mees (see "B.J.," June 7, p. 431), if he has not already a copy.

**TANK DEVELOPMENT.**—Yes, the grooved porcelain tanks are not suitable. A metal rack is meant, and a galvanised one would not

affect the developer. It is not necessary to alter the developer, all that is required is a shorter or longer stay in the developer. Reynolds and Branson, Leeds, make a special tank. A Standa tank may be had from any dealer.

**JIM.**—The thinnest plate you can possibly get. Hinton and Bedford Street, supply a special thin glass, which if you want would be 1s. 6d.

**H. N. A., PENARTE.**—It gives excellent results, clean, sharp, and in colouring when properly worked.

**REFLEX.**—The method you suggest is by far the most convenient, and, provided you have a first-rate lens, will give you results than taking direct in the large size.

**JEWELLERY LICENCE.**—Will you kindly oblige me by stating the extent a photographer may deal in gold locket, etc., and restrictions there are to his selling them?—QUERY.

No licence is required if the weight of the article is 2dwt. Above this weight a licence is required, and the following: Above 2dwt. and under 2oz. (gold), 46s.; above 2oz. and under 50oz. (silver) in one article, 115s. These are the restrictions.

**GLAZING.**—I should like to know, through your paper, how the high glaze on P.O.P. After mounting with paste it loses to a certain extent the glaze. I have tried putting through heated burnisher, but do not get the finish I should like. Is there any treatment before going through the burnisher? If so, I should be pleased to know.—P. C.

It would be advisable to back the prints whilst on the slab with waterproof paper, allow to dry, and strip in the way. The prints, before passing through the burnisher, be rubbed over with the following and allowed to get dry:—

Castile soap .....	2 ozs.
Water .....	4 ozs.
Methylated spirit .....	16 ozs.

Shave the soap small, heat up with the water, and add spirit slowly, with constant stirring, and allow to stand days, and filter.

**MR. WILLIAM FORD STANLEY, J.P.,** optician and scientific ment-maker, of Norwood, is to receive the hon. freedom borough of Croydon in recognition of the services he has rendered by erecting two public halls and a technical school at a cost of £50,000, and presenting them to the borough.

**WATFORD CAMERA CLUB.**—The fifth annual exhibition of the Watford Camera Club will be held on October 30 and 31 next. It will be seven open and seven members' classes, in all of which medals will be awarded. The award in the "champion" class will consist of a silver plaque, and the president, Lord Hyde, will present a special gold medal for the best exhibit in the members' class. Full particulars and entry forms (which will be ready shortly) may be obtained from the hon. sec., Mr. W. R. Ginton, 139, High Street, Watford.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received by the publishers, and advertisements are accepted on the understanding that they are absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**Net Convention.**—We publish this week the conclusion of the report of the Convention proceedings, together with a number of camera photographs of members who were present at the Hereford meeting. Mr. E. J. Humphrey's paper on a method of obtaining broad effects in contact printing appears on page 559. On page 560 will be found the paper by Dr. Mees and Mr. Wratten which are detailed experiments showing the very slight variation in the Watkins factor with the temperature of the developer or variations in the proportion of alkali. A brief report is given of Martin Duncan's lecture on insect life.

**Next year's Convention.**—It is to meet at Brussels, with Sir Cecil Leitch as President. (P. 564.)

**Correspondent raises an interesting point in commercial photography as to the making of a duplicate negative at the same time as the original which is being taken to a customer's order.** (P. 570.)

**Grimsby photographer was charged last week for Sunday trading the full fine of five shillings imposed, and 5s. 6d. costs.** (P. 569.)

**We publish some further explanations of the Workmen's Compensation Act in its particular applications to the professional photographer.** (P. 555.)

**Net Collodion.**—In this week's chapter Mr. E. W. Foxlee discusses the best formulae for development, intensification, and fixing, and some words to say on dark-room apparatus for the process. (P. 556.)

**The balance of advantage as regards depth of definition when using a short focus lens and enlarging as compared with taking a contact negative is mentioned in one or two notes of special interest to hand-camera workers.** (P. 553.)

**The importance of proper attention to the details of framing a photograph is emphasised in a note on page 554.**

## EX CATHEDRA.

### After the Convention.

Another Convention having come and gone, there is once more to be added to its pleasurable experiences the post-Convention satisfaction of having once again met old friends and once again made new ones. In a technical sense the Hereford Convention has not disappointed those who desire to emphasise the more serious side of it, but socially—and we would yield to none regarding the importance of the opportunities which the Convention supplies in this direction—the Hereford meeting has been every bit as successful as those of past years. One fact, we are sure, will be among the pleasantest recollections of the week in Herefordshire—namely, the personality of the President. Mr. Watkins, as a name in photography, has, of course, his place of honour, but many who had not known him personally must be grateful for a week spent in the society of a man, generous of his help and strength, and going about the multifarious duties of his office without one trace of ostentation. Secretary Bridge has done much for the Convention, but it is on him to induce the president for 1907 to desert his beloved Herefordshire for Brussels next year. We hope to see Mr. Watkins a factor in future Conventions.

\* \* \*

### Effect of Enlargement upon Depth.

This is a matter that very few people ever consider carefully, and one that with regard to which many are inclined to jump to erroneous conclusions. If a photograph is produced with a 5 in. lens working at  $f/8$ , and is enlarged up to whole-plate size, the result is the same as that which would have been produced by a 10 in. lens, so far as size of image is concerned; but if the 10 in. lens is to give the same depth, at what aperture must it be used? If this problem is put suddenly to the average photographer, he will in nine cases out of ten say "The same aperture," meaning that the 10 in. lens at  $f/8$  will give the same effect as the enlargement. As a matter of fact, however, the 10 in. lens must be used at  $f/16$ , for the rule governing the matter is that the two lenses must be used with apertures of the same diameter, if the larger print is to correspond in all particulars with an equal-sized enlarged copy of the smaller one. The misconceptions that prevail with regard to this matter are largely due to the very different rule that governs the production of equal depth in two direct images made by lenses of different focal lengths. If we want the same amount of depth in the image produced by the 10 in. lens as exists in the smaller image produced by the 5 in. lens at  $f/8$ , then the former lens must be stopped down to  $f/32$ . The difference between the two rules is, of course, due to the fact that in enlarging an image we increase, not

simply its size, but also in the same ratio the amount of confusion, or of want of definition. If photographs made by different lenses are to show the same depth when all are enlarged or reduced to one common size, then all must have been taken with apertures of the same diameter, as Mr. Debenham explained long ago.

### Long v. Short Focus Lenses.

The advantages of long focus are indisputable. From the pictorial point of view, the ideal focal length for use with quarter-plates is 10 in., but it does not follow that we should therefore equip our hand cameras with 10 in. lenses. If rash enough to do so, it is more than probable that our pictures will be either very few or non-existent. The trouble of want of depth will be too severe a handicap, for, to get as much as we want we must either stop down severely, or retire to an inconvenient distance. The former proceeding renders shutter work impossible, while the latter frequently spoils the perspective, and takes all the vigour out of the subject. As a matter of fact, it is often impossible to get far enough away, and with an extra long focus lens it is sometimes astonishing to note the apparently crowded state of the earth when we are trying to back away from a subject. With a short focus lens and subsequent enlargement, we can obtain just the result that in the majority of cases we want—that is, a narrow-angled moderately near view on a fair-size scale. The most useful function of long focus lenses in outdoor work is securing large-size distant views. For this and for portraiture, and indeed for any work in which great depth is not required, they are invaluable. For hand camera purposes, however, the necessities of exposure and depth can only be met satisfactorily with the aid of short focus lenses, while the advantages of long focus are reaped by subsequent enlargement.

### Advantages of Enlargement.

The facts given in the above note emphasise the most important advantages of using short focus lenses and enlarging the results. It is too commonly assumed that an image enlarged from a small negative is necessarily inferior to one taken direct with a long focus lens. If it is inferior, the deficiencies are due either to the use of indifferent apparatus and materials, or to faulty manipulation. Given proper appliances, and avoiding extreme degrees of enlargement which lead to coarseness of texture, an enlargement can be produced that leaves nothing to be desired in the way of quality, while it is quite possible that no useful result at all could have been produced directly with a long focus lens. Suppose, for example, the subject is one that necessitates a very rapid exposure. If the small negative is made with a 4 in. lens at  $f/5.6$  and enlarged four times, the result is equivalent to one produced with a 16 in. lens at  $f/22$ , but very probably at that small aperture no result at all could be produced. Hence by enlargement we have obtained a result that otherwise could not be secured at all.

### Sulphide Toning.

The results of some recent investigations into the secrets of sulphide toning seem to have aroused suspicions as to the permanency of the results, but we do not see that there is much reason for these apprehensions. The doubts seem to have arisen from the fact that the brown toned result is soluble in hot water. It, however, appears that it is a gelatine compound, and that it is soluble only under the same conditions as gelatine. It does not seem to be affected by cold water, and the inference is that it will last just as long as the gelatine. It is true that the solution shows a change in course of time. Black silver sulphide is precipitated

after long standing, but there is no probability of any such action taking place in the toned print, even if it did, it could only result in a slight darkening of the tone. Whether any such darkening has been noticed we do not know. As regards the effect of gaseous vapours on the result, a sulphide-toned print has the advantage over a plain silver print in that it is necessarily protected against sulphuretted hydrogen, which is the principal source of danger to a silver deposit. It is readily attacked by the halogens in the same way as silver, but these are rather unlikely sources of trouble. In any case, a coat of celluloid varnish offers a good protection without affecting the appearance of the print in any way. A likely cause of deterioration is the very slight wash that the toned prints too often receive. There seems to be an idea that washing is almost a superfluous item in this toning process, but if the chemicals used are perfectly removed, stained whites must appear sooner or later.

### Defective and Effective Framing.

When a framed silver print shows a diagonal line of discoloration straight across the picture, the cause can be immediately diagnosed without any further inspection. There is a split or an open joint in the backing board of the frame. We have seen many old photographs that have been ruined in this way, and an examination of many frames shows that there are numerous other photographs that are bound to go the same way sooner or later. The backing board, as a general rule, is a worthless piece of dead wood full of knot-holes and splits, and of no value whatever for the purpose for which it is used. Generally speaking wood is an unsuitable material unless it happens to be of especially good quality, and in any case it should always be backed with waterproof paper laid over the back of the mount. The usual thing is to cover the whole back of the frame with thin brown paper, but this is of very little use. It is easily torn, and affords very small protection even if untorn. The method of framing that we prefer is the following: Take a piece of Willesden or other strong waterproof paper rather larger than the mount, and lay it right over the back of the frame. Then take a good sound wood backing board, or, preferably, one cut from thick millboard, lay it over the waterproof paper, and press both down into the frame. After tacking in the backing board, the projecting edges of the waterproof paper can be trimmed off. Paper strips can then be pasted over the joins if it is desired to be quite on the safe side, but if the backing board fits tightly this is hardly necessary. Other advisable precautions are the use of well-made frames and good flat glass, so that such a space does exist, it is worth while lining the rebate with velvet strips or thick, soft blotting paper. Further it is never desirable that the print should touch the glass for if any condensation occurs on the inside of the glass the print will be ruined. A slip between the glass and the mount, or a cut-out mount, is therefore a desirable precaution.

"CORRECT EXPOSURE AT A GLANCE" is the title of a booklet compiled by the Rev. F. C. Lambert and Mr. William Tylar, which is designed primarily for the use of hand-camera workers. The length of exposure and stop to be used with various makes of plates, for all ordinary subjects, at different times of the day, in bright or dim light, are arranged in tabular form for each month of the year, and the exposures for rapid and extra-rapid plates being printed side by side in red and black figures respectively make the whole easy of reference. Copies of the booklet, which may be carried in the waistcoat pocket, can be obtained from William Tylar, 41, High Street, Aston, Birmingham, price 6d., post free 7d.

## WORKMEN'S COMPENSATION ACT IN RELATION TO PHOTOGRAPHERS.

the publication of some notes on this new piece of legislation in our columns some months ago the Act has come into operation, and since July 1 last its clauses will apply to all cases in which an employee claims compensation from an employer. It may therefore be of interest if we recapitulate some of the more important provisions of the Act, and particularly such as are of application in the photographic trades. This is all the more so from the fact that subsequent to the publication of the text of the Act several supplementary pamphlets have been issued by the Government in explanation of the somewhat intricate wording of the Act itself. The latter have been obtained for 3d., but the subsequent publications together 11d.

It is, of course, hardly necessary to point out that the Act applies to photographic as well as to all other trades. Photographers, who may perhaps only employ two or three hands in their business, may possibly imagine (for no reason that their places do not come within the scope of the Workshop Act) that they are exempt from the provisions of the Workmen's Compensation Act. Such is, however, a fallacy, and sooner it is dispelled the better. If only a single person is employed the employer is liable to pay compensation for any injury the employee may meet with in the course of his, or her, employment.

The new Act is a somewhat verbose one—some twenty pages—and by no means comprehensive to a layman. It seems to be bristling with technicalities from beginning to end. That being the case there is very little doubt that it will not be long before it will give plenty of work for gentlemen of the "long robe." The explanations already issued are really necessary for understanding how to proceed under the Act.

We shall here mention some of the liabilities that may be incurred by the photographer. For example, an employee, male or female, or an apprentice under the age of twenty-one earning less than twenty shillings a week, in case of injury, is entitled to be paid full wages after the first week of disablement up to ten shillings a week, until able to resume his, or her, duties. In the case of employees earning more than a pound a week the compensation is half regular wages, but such weekly payments are not to exceed twenty shillings per week. Unless the disablement continues for more than two weeks no compensation can be claimed for the first week. After twelve months of disablement the compensation may be increased to fifty per cent. of the weekly sum the employee would probably have received at that time but for the injury. For example, if an employee on an increasing salary the employee would be entitled to half what he would have been receiving at that time if he had been able to work. Where death results from the injury the employer has to pay to the dependants the sum of the employee's earnings "a sum equal to his earnings in the same period of the same employer during the three years preceding the injury, or the sum of one hundred and fifty pounds, whichever of those sums is the larger, but not exceeding in any case three hundred pounds, provided the amount of any weekly payments made under this Act and any lump sum paid in redemption thereof, shall not exceed from such sum, and if the period of the workman's employment by the said employer has been less than three years, then the amount of his earnings during the three years shall be deemed to be one hundred and fifty-six times his average earnings during the period of his actual employment under the said employer." We have quoted this portion of Section 1 of the first Schedule of the Act *in extenso* merely to show what are the liabilities of employers—photographic or otherwise.

It seems, according to the Act (we again quote from it), that "if it is proved that the injury to a workman is attributable to the serious and wilful misconduct of that workman, any compensation claimed in respect of that injury shall, unless the injury results in death or serious and permanent disablement, be disallowed." This appears to be very hard upon the employer, as apparently he is responsible for the employee's wilful misconduct if it results in his death or permanent disablement.

If an employee contracts a disease during his employment, due to the materials used in the business, he is to be compensated as in the case of accident. Amongst the diseases named in the schedule are lead poisoning and mercury poisoning, and since the Act itself was printed an additional Schedule has been added to it, which may have far-reaching consequences to photographers. It may, therefore, be of interest to quote from the "Statutory Rules and Orders, 1907, No. 407." "Now I, the Right Honourable Herbert John Gladstone, one of His Majesty's Principal Secretaries of State, by this Order, made under Sub-section (6) of the said Section, do hereby direct that the provisions of Section 8 of the Workmen's Compensation Act, 1906, shall extend and apply to the diseases, injuries, and processes specified in the first and second columns of the Schedule annexed to this order, as if the said diseases and injuries were included in the first column of the Third Schedule to the Act, and as if the said processes were set opposite in the second column of that Schedule to the diseases or injuries to which they are set opposite in the second column of the Schedule annexed hereto." From this it will be seen that power is given under the Act to add, at any time, other diseases that may be caused by the materials used in any trades. It is not necessary here to enumerate all the diseases mentioned in this new Schedule, but it may be said that in the Schedule of the Act itself only six are included, whereas in the new one eighteen more are added. Here are those that are directly connected with photography:—

### SCHEDULE.

DESCRIPTION OF DISEASE OR INJURY.	DESCRIPTION OF PROCESS.
1. Poisoning by nitro—amido—derivatives of benzene (diamido-benzol, aniline, and others), or its sequelæ.	Any process involving the use of nitro—or amido—derivatives of benzene, or its preparations or compounds.
3. Poisoning by nitrous fumes or its sequelæ.	Any process in which nitrous fumes are evolved.
8. Chrome ulceration or its sequelæ.	Any process involving the use of chromic acid or bichromate of ammonium, potassium, or sodium, or their preparations.

Now it is clear that the first item includes nearly all, if not all, the new developers. Hence, it will be noted that if any employee suffers from using, say, metol, amidol, or any of the other bodies, and is thereby incapacitated from doing his usual work, he will have to be paid half his, or her, usual average earnings up to a pound a week. If the employee is under the age of twenty-one, and his average earnings are less than a pound a week, he must be paid full wages, but that payment is not to exceed ten shillings a week. The third item, "poisoning by nitrous fumes," is of importance to photo-etchers when they employ nitric acid in the etching. If a worker suffers injury from the fumes given off during his work he is entitled to compensation. Therefore process-block makers and the like will do well to see that the work-rooms where this portion of the work is done are well ventilated. The eighth item, "chrome ulceration," is of special importance, seeing that the bichromate salts are now so largely employed in many different processes of photography. If an employee, for instance, working any process in which these salts are employed, suffers ill effects from their use he can, of

course, recover compensation for the injury in the same way as if he had been incapacitated by an accident.

The compensation to be paid for temporary disablement, as just intimated, is half the weekly wages until recovery, but it is not to exceed a pound a week. The liability for permanent total disablement is, perhaps, the most serious of all for the employer, as it is half the weekly wages for life, which in the case of a young person might amount to a very large sum. It should be mentioned that employees who are paid £250, or upward, a year do not come under the new Act.

The generally exacting tone of the Act calls for the most serious attention on the part of photographers, for neglect of their liabilities may mean ruin to a photographer in a small way of business. We cannot too strongly insist on the advice that all photographers who employ assistants will do well to insure every hand, even down to the errand boy. It is not necessary to insure them individually. The offices will insure them *en bloc* in accordance with the gross salaries paid. The premiums are really very small indeed, in consideration of the liabilities thrown on employers, and of the fact that the policy relieves them of all risks.

Those who do insure, and most we assume in their own interests will do so, should read carefully through the policy when received, and make themselves fully acquainted with its conditions, so that they may all be fulfilled, for unless that is done no claim under it can be legally sustained. In one policy we have seen, in which the errand

boy is included, it is mentioned, "without bicycle refer to this as an example of minor conditions that be included in a policy. In this case, if the lad man an accident when riding a cycle while on his master's business, no compensation would be paid by the insurance company. It is the master who would have to compensate himself as laid down in the Act; his insurance would not cover it. We merely mention this to illustrate the necessity there is that all policies be read and digested.

To repeat what we have already said in other issues, the insurance of their employees is a duty which photographers owe to themselves and those dependent on them. In a prospectus of an insurance company now before me we note that photographers are classed amongst chemists, bakers, drapers, florists, jewellers, stationers, and the like, and the premium charged to them is four shillings per cent., the premiums being payable on an estimate of total wages and salaries for twelve months. For other trades the premiums are much higher—amounting in some cases to fifteen shillings per cent. Although we have only consulted the prospectus of one office we surmise that the tariff with all is much the same. In conclusion, we may add that members of the Professional Photographers' Association can obtain a policy at a reduced rate, as the Association has arranged with an insurance company granting policies, as they do those against fire, under the Workmen's Compensation Act, at a considerable reduction on their usual tariff.

## THE WET COLLODION PROCESS IN PRACTICE

[Former articles of this series having dealt with the preparation and care of the silver bath, the following article describes the development of the plates, and succeeding contributions by Mr. Foxlee will deal with further manipulation in sensitising and development.—Eds. "B.J."]

At one period of the collodion process pyrogallie acid was the universal developer for negatives. It has, however, been long superseded by iron, and pyrogallie acid is now only used as an intensifier after the image has been fully brought out by the iron developer. In the text books, the photosulphate of iron is given in all the formulæ, but the ordinary sulphate of iron—the green copperas of the druggists or oilshops—is far preferable, as it yields more density in the negatives.

### The Iron Developer.

The crystals of the pure photosulphate are of a pale green colour and are free from oxidation, and give a pale apple-green solution. Those of the common sulphate are usually oxidised or rusty at the edges, and give a more or less dark sherry coloured solution. In theory, a developer made with this, weight for weight, is not quite so energetic as the other, but this is compensated for by using a little more of the salt. In purchasing the common sulphate it is necessary, however, to see that the crystals are perfectly dry. If they are at all wet or damp, the salt should be rejected. The following is a very good formula for the iron developer:—

Sulphate of iron .....	2 ozs.
Glacial acetic acid .....	3 ozs.
Alcohol .....	1 to 2 ozs.
Water .....	1 quart.

The solution should be filtered. In cold weather the proportion of acetic acid may be reduced to, say, 2½ ozs., and in hot increased to 3½ ozs. or even 4 ozs., with advantage. For the alcohol, methylated spirit, if free from the mineral spirit,

answers quite as well as pure alcohol. The spirit really has no part in the development of the image; its only use is to cause the developer to flow freely over the plate, thus avoiding stains. When the silver bath is new, very little spirit is required for the purpose, but when it gets old and well charged with ether and alcohol, from the collodion, a larger proportion must be used.

In my own practice I make up a good quantity of the developer of four times the strength just given, and then dilute it with one part of water, or one pint or two at a time, for use. The advantage of doing this is that what sediment there may be in the solution has time to subside in the stock bottle, and the clear portion can be decanted as required for dilution. In this way the trouble of filtration is avoided. If the crystals of sulphate of iron are but slightly rusted, I usually, after they have dissolved, add a few drops of liquor ammonia, so as to precipitate a little of the iron, which is redissolved when the acetic acid is added, but with the commercial sulphate—copperas—this is not required. Some operators add a certain proportion of sulphate of copper to the iron developer, but the practice is less general here than on the Continent. In Germany I have seen as much as twenty-five per cent. of copper used with the iron developer. Personally, I have not found any great advantage in the use of copper, except, perhaps, that it gives a rather more non-actinic character to the image. Certainly it does no harm whatever, even if it does no good.

### Intensification—i.e., Extra Development.

The intensifying solution is very similar to the pyrogallie acid developer that used to be universally employed to

t the developer proper, except that it is usually made somewhat stronger. A formula is:—

Pyrogalllic acid .....	100 grs.
Citric acid .....	$\frac{1}{2}$ oz.
Water .....	20 ozs.

Instead of using citric acid alone, I prefer to employ a smaller quantity of it and supplement it with acetic acid. The intensifying solution I usually employ is:—

Pyrogalllic acid .....	$\frac{1}{2}$ dr.
Citric acid .....	1 dr.
Acetic acid (glacial) .....	1 oz.
Water .....	20 ozs.

Negatives intensified by this formula have a browner and more non-actinic colour than when the larger proportion of citric acid alone is employed. It is not advisable to make up a large stock of this—as with the iron developer—as it does not improve keeping. Sufficient for several days' work may, however, be prepared at a time. When the intensifier is used, it is necessary to add a little solution of nitrate of silver to it. Some operators used to add a drop or two of the silver bath, dropped from the dipper; but this practice is not to be recommended, because the bath silver is sometimes very quickly reduced in the intensifying solution, causing it to become muddy and of no effect. It is much better to make up, and keep at hand, a new solution, such as the following:—

Nitrate of silver .....	2 drs.
Distilled water .....	20 ozs.

This is conveniently kept in a corked bottle, with a notch cut in the cork so that a few drops can be shaken out as required.

### Fixing Bath.

For fixing collodion negatives we have the choice of two agents—cyanide of potassium and hyposulphite of soda. The former, as is well known, is a deadly poison, and should not be allowed to enter cuts or abrasions of the skin; but it is the one I prefer, and although I have fixed some tens of thousands of negatives with it—extending over several decades—I have never offered the slightest inconvenience from its employment. But I have always handled it with moderate care. With regard to the strength of the cyanide solution, nothing very definite can be said, as various samples of cyanide differ materially in quality. But if it be got from a reliable house, as a rough guide 10 grs. to the ounce of water will be about the right proportion. In practice it is very usual to put a few lumps in a wide-mouthed stoppered bottle and add some water; this will give us a more or less saturated solution. Then, having another wide-mouthed bottle handy—say standing in the corner of the sink—a little of the strong solution is poured in and water added. One soon learns the quantity. The strength of the fixing solution should be such that the unaltered iodide of silver is completely removed in from one to two minutes. The solution may be used over and over again—being strengthened from time to time as it loses its fixing property. If the cyanide fixing solution is used too strong, it has a tendency to dissolve some of the more delicate half-tones of the picture, therefore it is best to use it well diluted and allow a longer time for its action. The solution can be used in a dipping bath or in a flat tray, or it may be merely poured on and off the plate, like the intensifier. When the bath is used the solution is generally made weaker than when it is simply poured over the plate.

The hyposulphite of soda is a very general fixing agent for collodion negatives, but its solution is used much stronger than for gelatine plates. A very general solution for collodion negatives is:—

Hyposulphite of soda .....	$\frac{1}{2}$ lbs.
Water .....	1 quart.

This solution, like the cyanide, can be used over and over

again, or until it becomes exhausted. Its becoming discoloured is of little moment in the collodion process. This, like the cyanide, can be used as a bath, and it is best to use it in that way, as it is slower in action than the cyanide. The "hypo" fixer does not give quite such transparent shadows as the cyanide, though there is not much difference. Therefore the latter is the preferable when, as in some of the mechanical processes, absolutely clear glass in the shadows is essential.

### Dark-Room Equipment.

Supposing the chemicals, as already described, are ready for use, we will now proceed with the manipulations. Before doing so, however, it may be as well to say a little about the dark-room. Compared with gelatine the collodion is a slow process, therefore a much more comfortable light to work in is quite permissible. Those familiar with the former process only, when they see a dark-room for working the latter, are usually forcibly impressed with the large amount of light there is in it. A window two to three feet square, covered with a couple of thicknesses of orange-coloured paper, is generally quite a safe light with collodion plates. If the window faces the north, even a single thickness of canary medium will usually suffice, or a single thickness of deep orange glass will also be sufficient.

It is not advisable to have artificial light in the dark-room, unless it be the electric, as the vapour of ether is so highly inflammable, and there would be a risk, in coating large plates, of its taking fire if it came in contact with a flame. If artificial light other than electric has to be used, the lamp should be situated somewhere above the level at which the plates are coated with the collodion, as the vapour of ether, being considerably heavier than air, sinks down. Whatever light be adopted, it is well to test it by sensitising a plate, putting it into a dark slide, partially withdrawing the shutters, and exposing it for a minute or two to the light, at about the distance the plates are developed. If on development there is no fog on the exposed portion, the light may be considered perfectly safe, even though there is so much of it as compared with the dim light imperative with rapid gelatine plates.

With regard to the arrangement of the dark-room, nothing special need be said, as any ordinary room as used for dry plates is suitable. The silver bath, however, should be so placed that the light from the window or other light takes it, so that when the plate is out it can readily be seen whether it is free from the streakiness due to the solvents of the collodion. It should be specially mentioned that the room must be perfectly free from dust, as any particle settling on the film will produce a spot or "comet," which cannot afterwards be got rid of. Dust settling on a dry plate can be wiped off; not so, however, in the wet collodion process—it is certain to cause a blemish of one kind or other in the negative.

The ordinary dark slides, as used for dry plates, are of no use for wet collodion plates. The slides or carriers must be furnished with silver wire corners for the plates to rest against. If they were put into the rabbets of the usual slides the margins of the negatives would be strained from the wood; also the film would be damaged at the edges, and would be liable to wash up in the after operations.

### Receptacles for Collodion.

The collodion in use is best kept in a tall bottle, so that any particles of fluff or dust that happen to be on the plate at the time it is coated and is carried off by the collodion can settle down out of the way before the next plate is coated. Tall bottles with a large lip, and furnished with a cap instead of a stopper, are specially made for the purpose, and can be obtained from all the large dealers. If an ordinary stoppered bottle be used, and the plates to be coated are large, it is well to have a small funnel in its neck into which the collodion can be drained

off as the plate is coated. But with small plates this is not, at all necessary. The coating of a plate with collodion is looked upon by some as a difficult operation, but it is really a very simple one after a little experience is acquired. It is quite as easy as varnishing a dry plate; indeed, easier, perhaps, as the collodion flows over the cleaned glass somewhat more freely than does the varnish over the gelatine film.

#### Plate Holders.

If the plates are small, say 12 by 10 and under, they may be held by the corner between the thumb and forefinger, but the other fingers must not be used to support the plate or the heat from them would warm the plate, especially if the glass were thin, and would cause the solvents of the collodion to evaporate more rapidly were they touched, and with the result of an unequal coating, which would show in the negative. If, however, the plate is too large or heavy to be conveniently held by the thumb and finger without the other fingers' support, the latter may be employed, provided that four or five thicknesses of stout blotting paper, which is a fairly good non-conductor of heat, intervene between the fingers and the glass. If large plates have to be dealt with, they must have some support, and most operators have a contrivance of their own for the purpose. One of the most convenient I have seen was in an establishment in Germany. It was quite a home-made affair. The base was a piece of stout board 10in. or 12in. square. In this was fixed an upright, also of wood, about 12in. or 15in. high, and on the top of this was fixed a stout circular piece of wood 6in. or 7in. in diameter, with the upper side somewhat rounded. The plate supported on this could be most conveniently manipulated. Two of these holders were provided in each dark room, one being kept on a bench and used solely when coating the plates with the collodion; the other stood in the sink, and was used only in the development of the negatives, which were usually of very large size.

Coating is done in the following way: After the plate has been

cleaned in the way described in a former article, it is held with a broad camel-hair brush, or, better still, with a hair brush. It may be incidentally mentioned that it is better to let the plates rest for a short time after polishing, as glass is then in a more or less electrical condition and attracts dust. The neck of the bottle, outside and in, is freed from dried collodion and dust; then, holding the plate horizontally by one corner, a good pool of the collodion is poured at the centre. The plate is then slightly tilted so as to cause the collodion to flow up to the further right-hand corner, and then to the left.

#### How to Coat a Plate.

The plate is then slightly raised so that it flows to the nearest left corner, avoiding the thumb, and then to the remaining corner, where it is drained off into the bottle. While the collodion is draining off the plate is gently rocked from side to side to avoid crapy lines. The coating of the plate should be done slowly and deliberately, and on no account should the collodion be permitted to flow over any portion a second time, as this would be certain to produce an uneven coating. In draining the collodion the plate should only be slightly tilted at the corners particularly if it is of large size, for, as just mentioned, the vapour of ether is heavy; and if the plate is kept nearly horizontal, and is not breathed upon to create a draught, a large pool of it will rest on the plate, and to a great extent retard the action of the collodion until the larger part of the excess has drained off. Then the plate can be gently brought to the vertical position, still rocking the while. When the collodion has drained off roughly set, which will take some seconds, according to the temperature, it is ready for the sensitising bath. It must be kept out too long, neither should it be immersed too quickly. As a guide for the time for immersion, it may be mentioned that when the collodion at the corner from which it was drained takes an impress of the finger the plate is ready for the bath.

E. W. FOXALL

## THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

THE brilliant outburst of summer weather which favoured the Convention for the first three days of last week (the period covered in our issue of the 19th inst.) did not disappoint conventioners during the latter part of the meeting. Thursday, on which day there was an outing to Ludlow, was as hot as was consistent with comfort and photography. The weather also was equally favourable on Friday and Saturday, when Goodrich Castle and Ledbury were visited.

But the most enjoyable event of the week was most certainly the garden party, to which, on the Wednesday afternoon, the President and Mrs. Watkins invited the members to their home—the Vineyard Croft, on the banks of the Wye, about a mile from the city. Naturally picturesque, the garden and shrubbery, sloping abruptly to the river, were rendered still more attractive by sunshine falling on a goodly company of ladies and gentlemen. Many were content to rest within cool shade, while others, more adventurous, put off upon the rapid Wye in boats and punts. All, however, were agreed that no more charming host than Mr. Watkins could be found, and when the afternoon was gone it was with feelings of reluctance that the company returned to the centre of the city, having been entertained in characteristic cordial homely Herefordshire fashion.

The annual dinner took place on the Wednesday evening at the Green Dragon Hotel. Mr. Watkins presided, and was supported by the retiring president (Mr. E. J. Humphery), the Mayor of Hereford (Alderman C. G. Caldwell), Mr. F. A. Bridge, and Mr. W. T. Carless.

After the customary loyal toasts, "The Photographic Convention of the United Kingdom" was proposed by Mr. H. Snowden Ward. Mr. F. A. Bridge, in replying, said he felt sure that the meeting in

Brussels next year would be attended by many who for sentimental or other reasons were in favour of the meetings being confined to the United Kingdom. It was a pleasure for him to work for the Convention, and he looked forward to a most successful meeting in Belgium.

Mr. Bridge then proposed the toast of the Herefordshire Photographic Society, coupled with the name of Mr. W. T. Carless, one of its members, who had acted as hon. local secretary to the Convention, and to whose powers of organisation and capacity for work the success of the Hereford arrangements were largely due.

Mr. Carless suitably responded.

"The City of Hereford" was proposed by Mr. C. H. Botham in response to whose remarks the Mayor of Hereford referred to steady progress of the borough and to the success with which it had undertaken the municipalisation of such public services as lighting and water supply.

Mr. Alfred Ellis proposed the toast of "The President," in response to which Mr. Watkins recalled his life-long connection with the county of Hereford, and expressed his pleasure in introducing members of the Photographic Convention to scenes and places which many years had been the delights of his life.

The toast of "The Press" was proposed by Mr. E. J. Humphery in a pseudo-pessimistic speech of no little humour; response to which was made by Mr. G. E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY) and by Mr. A. Horsley Hinton ("The Amateur Photographer"). The toast of "The Ladies," proposed by Alderman Beddoe, and responded to by Mr. Snowden Ward, brought the proceedings of the evening to an end.

Owing to the unavoidable absence of the authors, the paper by C. E. K. Mees and Mr. S. H. Wratten on "Variations in the Watkins Factor" was read by Mr. G. E. Brown. The text of the paper is given on page 560.

The short abstract of the lecture by Mr. Martin Duncan, which we publish, is not by any means a fair representation of a discourse which proved fascinating in the extreme, and kept a large audience

interested from the beginning to the end on the Friday evening. Mr. Duncan's cinematograph photographs of insect life are of a kind which cannot be adequately described by any verbal method. They must be seen to be appreciated, and the interest with which the lecture was received leads us to hope that so long as Mr. Duncan continues to apply his technical powers in this way a lecture by him ought to be an annual feature at the Convention.

### AN AID TO PICTORIAL PHOTOGRAPHY.

(A paper read by Mr. E. J. Humphrey before the Photographic Convention on July 18.)

Trusting that the few remarks and examples of work which I am about to submit to you may be of service to two very different classes: 1st. To those who are so busy that they find it difficult to obtain a sure.

2nd. To those who have so much leisure that they would like to have some congenial work found for them.

In the first class we find the professional photographer, whose sitters wish to obtain finished pictures almost as soon as the negatives are ready. These customers recognise no speed limit and expect the unfortunate artist to scorch all the time, however heavy his petrol consumption must be to enable him to dry off his negatives.

The President, Mr. S. H. Fry, and Mr. A. Horsley Hinton.

He is then confronted with the delay caused by the retoucher, and not delay only, but the risk that the very charming ladies who do this work have in many cases never seen the sitter and so spoil the likeness, sometimes, alas! giving an old man, with a grand, rugged face, full of character, the complexion of a ruddy cherub in waxwork, or possibly failing to understand the aims of the artist, utterly ruin the gradations of light and shade, which are the very soul of the picture.

The examples I now submit to you show how these risks may be avoided.

The method is quite simple and inexpensive, and can be varied to suit the taste of the artist to any extent.

To obtain the results shown in the first examples I stretched on the wall a piece of common packing canvas, took a negative of this, the size of the picture to be treated, developed it lightly so as to obtain a clean transparent negative, which I now submit to you.

This negative and that of the portrait are put together in the printing frame, the paper placed in contact with the portrait negative, and exposed to the light of an arc lamp or direct sunlight, the rapidity of printing being very slightly affected.

The result, as you will see, entirely does away with the necessity of retouching, preserves the character of the face, and gives the appearance of a picture on linen.

The coarseness or fineness of the canvas effect can be obtained from the same piece of material by altering the distance of the lens from the fabric to be photographed. This is the simplest method which I have to show, but various other effects can be obtained by a modification of the process. First, we will suppose a negative of very hard contrast, in which it is desired to tone down the harshness of the

Convention Makers—Secretaries F. A. Bridge and W. T. Carless.

high-lights. In this case it is advisable to print the portrait negative alone, and then replace it with the fabric negative, and expose for a minute, or as much longer as may be desired. This not only softens the high-lights, but gives great transparency and luminosity to the shadows.

The two pictures of the monk knitting, which I will now hand round, show a variation of this method. That on the left was printed under both negatives at once, but the background was so dense that the fabric negative was quite blocked in that part. To get over this fault, in the right-hand picture after the first exposure under the two negatives, the portrait negative was removed, the fabric one left, and a short exposure was given, softening down the harsh white of the background, and giving a soft and more pleasing effect.

The next picture I have to show you is perhaps rather too broad in treatment to suit most tastes, but possibly it may appeal to some of the Salon artists—it must not be viewed at too short a range.

In this case, instead of using canvas, I have taken common rough

Russian bass matting, usually used by gardeners to cover cucumber frames, photographed it in just the same way as the canvas, and substituted the negative for the fabric negative shown before. This, however suitable for broad effects, should not be used for pictures of young girls, as it would probably be considered by their mammas too bold.

However, if you do not like it for the picture you can use it for the margin, as in the picture of Mr. Smith, which I will show you.

I have here a table and some trays decorated in this way which will exhibit first, and then describe the method of working.

It will probably be found best, first, to prepare the various of mounting board to which the prints are to be affixed.

These should be cut in rectangular form, so that they may be tailed one into the other.

When a sufficient number of these have been prepared, the prints should be mounted thereon, being just a shade larger than the

"Honest Tom" (T. Scotton) sets up his "Sanderson."

Dr. W. Scheffer "enlarges" to Mr. S. H. Fry.

A momentary respite from narrative fiction.

The Editors of the "Photographic Monthly."

#### PERSONÆ OF THE CONVENTION.

In this the portrait and fabric negative are printed together, again without any retouching, the margin being masked. When the picture is sufficiently printed, it is masked, and the Russian matting negative used with a graduated exposure of from one to six minutes.

This effect can be modified by using both the fabric and matting negatives together, the fabric breaking up the crude pattern of the matting.

We now come to the second class, those who have plenty of leisure, and, I may add, plenty of patience also.

The examples which I am about to show you are the work and invention of Mr. Smith, whom you all know.

The idea is to use photographs for decorative purposes, giving the impression of tile or mosaic work.

the reason for this being that it is then much easier to trim the paper, face up on your work table, and rub down the edges of mounted prints.

To obtain this all that is necessary is to place a piece of fine glass paper, face up on your work table, and rub down the edges of mounted prints.

When your prints are all prepared, arrange them in the form which seems most desirable, and then take the pieces one by one and mount them to the material on which they are to be mounted.

E. J. HUMPHREY.

#### VARIATIONS IN THE WATKINS FACTOR.

[A paper by Dr. C. E. K. Mees and Mr. S. H. Wratten before the Photographic Convention, on July 18, 1907.]

THE name of our president is associated in such a unique way with the relation of the time of development to the time of the first appearance of the image, that it seemed to us that the publication of some measurements which we have recently made in our laboratory upon this subject must almost necessarily be made at the Hereford Convention of 1907.

The system of factorial development designed by Mr. Watkins has obtained a renown and adoption upon which there is no need for us to comment, but it is noteworthy that, during all the years of its use, there has been practically no publication of definite measurements made with a view to confirming the original basis on which it is erected.

In order to get an idea of this basis, let us consider development as taking place in a film which consists of a number of cells of gelatine with fairly continuous solid walls, and separated by a network of open passages, with each cell inhabited by a grain of silver bromide.

The best comparative picture that we can give would be that of a maze with wide open passages, along which the children can run without hindrance, but with a great many little cells surrounded by good stout hedges offering a definite resistance, even to a small boy

desirous of getting at the apple tree which occupies the centre of each cell. Our developer penetrates the passages of the film with great velocity, and then slowly diffuses through the cell walls to attack the silver bromide.

The first thing that happens to the silver bromide grain is necessarily the solution of some portion of it, because only in solution of reaction, of the kind that we are considering, take place. The dissolved silver bromide, representing, of course, only an infinitesimal portion of the grain itself, re-acts with the developer and produces metallic silver in solution, and the first part of the development reaction consists in the saturating up of that metallic silver to a point at which it must either precipitate or stop the reaction and the solution of more silver bromide.

Now the silver cannot precipitate unless it has a nucleus, and it is the function of the much discussed latent image to furnish the nucleus. Whatever the latent image consists of, it may be considered for the purposes of development, as simply the nucleus in each cell for the deposition of silver. If you take a beaker containing a supersaturated solution of hypo which has cooled to the point at which it is ready to deposit its hypo at the slightest incentive, then the introduction of any disturbing medium will determine the precipitation

the best medium of all is, of course, a crystal of hypo itself. And our cell containing a super-saturated solution of silver.

spect of foreign matter of any kind will produce deposition of silver, but the true nucleus is a latent image produced by the exposure of that grain to light. Once silver is deposited, that grain is easily developable, because silver bromide continuously dissolves and takes up for that which has been reduced, the developer flows to replace that which has been used, and the oxidation products out of the cells and through the wide passages of the film. The time of development from that time on is determined, no longer by the rate of reaction of the silver bromide, but by the rate at which the developer can reach the grain, and the oxidation products can be removed—viz., the rate of diffusion through the cell wall.

That we have two stages in development: the first determined at the beginning by the amount of time necessary to produce super-saturation of the silver to the necessary degree, and the second determined by the penetration of the developer into the film. The second stage is much longer duration than the first, and settles the form of the development equation. This form will be of somewhat the same for all developers.

Now let us define the "Watkins factor," which we may term F. We take for a definite exposure a density D, to which we wish to develop that exposure, then we shall reach that density D in time T with any given developer. And if we call the smallest density which

is obtainable with a given developer Da, then this will appear in time Ta, so that  $F = \frac{T}{Ta}$ .

"F" is dependent on the second stage of the development, but Ta is most entirely dependent on the first stage, which will vary with different developers, and probably with such things as concentration and temperature, or the amount of free alkali, in a totally different way from one in which those things will affect the second stage; so

one would expect  $\frac{T}{Ta}$  that is, the Watkins factor, would not

be independent of the developer, nor would it be independent, at least completely, of the temperature and of the concentration. Watkins has already stated that it is generally independent of temperature and of the amount of free alkali, and that for some developers it is generally independent of the concentration, though for others it may vary.

In order to follow out a little more closely the idea which we have put forward as to the basis of the Watkins factor method, we have made in our laboratory a number of measurements of these variations with the greatest accuracy to which we could attain. The method employed was as follows:—

A large number of "ordinary" plates were coated on patent plate with the usual precautions of rejections of edges, etc., and were cut into one-inch strips; these were uniformly exposed in the sector wheel machine, and were developed in a developing thermostat in developers of the concentration and at the temperature given. When not otherwise stated, the temperature may be taken as 20 deg. centigrade. The plates were placed in the developer, and the time of appearance of the first stop-watch; the time of appearance was then multiplied by a guessed factor, and development was carried to the calculated time. After fixing and washing, the plates were measured, and from the measured development factor and the known constant of the plate the time was calculated which would have given a development factor of 8, this was taken as T, and on being divided by the time of appearance gave the Watkins factor.

The following example will make these measurements clear:—

#### VARIATION OF CONCENTRATION WITH HYDROQUINONE.

	$\frac{M}{10}$ (Assumed factor 8 except where 5 was taken).			
Strength .....	M	M	M	M
	10	20	40	80
Time of Development (secs.) .....	36	67	145	300
Time of Development obtained .....	130	536	1160	2400
Time of Development calculated .....	97	124	130	126
Time of Development .....	141	280	565	1220
Time of Development .....	3.9	4.19	3.9	4.08

Note.—The method of calculation for T calculated is as follows:—

Previous measurements of the  $\gamma_{\infty}$  for this plate had shown it to be 2.06.  $K = \frac{1}{t} \log_e \frac{\gamma_{\infty}}{\gamma_{\infty} - \gamma}$  where t is the actual time of development to get a development factor  $\gamma$ . Thus for the  $\frac{M}{10}$  Hydro-

quinone above  $K = \frac{1}{180} \log_e \frac{2.06}{2.06 - .97} = .00351$ .

T calc. =  $\frac{1}{K} \log_e \frac{\gamma_{\infty}}{\gamma_{\infty} - .8} = \frac{1}{.00351} \log_e \frac{2.06}{2.06 - .8} = 141$ .

This method assumes the truth of the equation used, but care was taken that the  $\gamma$  obtained was not far from .8.

#### DEVELOPERS USED

The developers were made by taking as unit a proportion of the molecular weight in grams of the reducer dissolved in 1 litre of water, containing the same proportion of the molecular weight in grams of sodium sulphite, and adding an equal quantity of a solution containing a proportion of sodium carbonate.

Thus the Molecular weight of Hydroquinone is 110  
 " " " Sodium Sulphite is 252  
 " " " Sodium Carbonate is 236

The standard developer of Hydroquinone contained:—

$\frac{M}{10}$ Hydroquinone .....	11 grams per litre.	$\frac{M}{10}$ being the molecular weight.
$\frac{M}{10}$ Sulphite .....	25.2 " " " "	
$\frac{M}{10}$ Carbonate .....	114.4 " " " "	
2.5		

This is termed in the Tables  $\frac{M}{10}$  Hydroquinone;  $\frac{M}{20}$  Hydroquinone contains half of the above constituents.

Metol standard was:—

$\frac{M}{20}$ Metol .....	17.2 grams per litre.	
$\frac{M}{20}$ Sulphite .....	12.6 " " "	
$\frac{M}{5}$ Carbonate .....	57.2 " " "	
Ortol. Same as Metol .....	$\frac{M}{20}$ Ortol	= 11.7 grams per litre
Pyro. Same as Hydroquinone .....	$\frac{M}{10}$ Pyro	= 12.6 " "
Amidol. ....	$\frac{M}{10}$ Amidol	= 14.5 " "
	$\frac{M}{10}$ Sulphite	= 25.2 " "
	$\frac{M}{5}$ Carbonate	= 57.2 " "
Pyrocatechin. ....	$\frac{M}{5}$ Pyrocatechin	= 22 " "
	$\frac{M}{5}$ Sulphite	= 50.4 " "
	$\frac{M}{2.5}$ Carbonate	= 114.4 " "

The results obtained were as follows:—

#### 1.—CONCENTRATION VARIATION.

(a) Hydroquinone.	M	M	M	M
Strength	10	20	40	80
Factor	3.8	4.19	3.9	4.09

Conclusion:—The variation with concentration is very slight.

(b) Pyro.	M	M	M	M	M
Strength	10	20	40	80	160
Factor	7.3	8.0	10.3	12.1	20.9
Conclusion:—Variation very small at ordinary dilutions, considerable at great dilutions (possibly owing to progressive oxidation).					

(c) Metol.	M	M	M	M	M
Strength	—	—	—	—	—
Factor	33.5	39	48.5	58	72.5
Conclusion:—Steady decrease in the Factor with increasing dilution. Ta for — and — too short to be trustworthy.					

(d) Ortol.	M	M	M	M	M
Strength	20	40	80	160	320
Factor	8.6	13	22.5	28.8	38.2
Conclusion:—As Metol.					

(e) Amidol	M	M	M	M	M
Strength	20	40	80	160	320
Factor	57	61.5	87	128	180

Conclusion:—As Metol. Ta for  $\frac{M}{20}$  untrustworthy. Oxidation very marked, due to use of Carbonate with Amidol.

(f) Pyrocatechin	M	M	M	M	M
Strength	5	10	20	40	80
Factor	3.36	3.67	7.6	11.9	15.0
Conclusion:—As Metol.					

(g) Rodinal Ready-made solution used.	1	1	1	1	1
Strength	10	20	40	80	160
Factor	14.5	17.3	20.4	30.6	46.9
Conclusion:—As Metol.					

General Conclusion:—The factor is variable with most developers when the concentration differs, increasing with decreasing concentration.

## 2.—TEMPERATURE VARIATION.

(a) Hydroquinone Temp. C.	10°	15°	20°	25°	30°
Factor	3.48	3.36	3.8	4.4	4.46
Conclusion:—The factor is practically independent of the temperature.					

(b) Rodinal Temp. C.	15°	20°	25°	30°
Factor	16	17.5	19.7	22
Conclusion:—Factor slightly variable with temperature.				

## ALKALI VARIATION.

(a) $\frac{M}{10}$ with respect to Hydroquinone.	M	M	M	M
Alkali	5	10	20	40
Factor (means)	5.4	5.7	4.9	6.3

Note.—These alkali variations gave very variable and inaccurate results.

(b) $\frac{M}{10}$ with respect to Pyro	M	M	M	M	M
Alkali	2.5	5	10	20	40
Factor (means)	6.59	5.89	8.16	8.8	6.8

Conclusion.—The factor is independent of alkali variation. It can be shown by mathematical reasoning that the factor is independent of the velocity of development, and very nearly independent of the ultimate density-giving power of the plate, so that the factor will not be dependent on the plate used.

In conclusion, our experiments confirm the practical results which are well known by users of our President's renowned method of development, and may be of some slight interest in their bearing on the nature of development.

The necessary measurements were made in our laboratory by E. F.

Witthaus; we have also to thank Dr. S. E. Sheppard for on the theoretical aspects of the matter.

Research Laboratory, C. E. KENNETH  
Wratten and Wainwright, Ltd., S. H. WRATTEN.  
Croydon.

The paper by Dr. Mees and Mr. Wratten was followed by discussion.

Mr. Alfred Watkins said that the results which had been were of course very satisfactory to himself. The work of the factorial system was based had been done some fifteen years when the need of accurate measurements was not recognised as it was at present. The important part of the paper, he considered was that relating to the effect of temperature. In practice a grapher need not and naturally would not vary his develop-

Colour Photography.—Mr. Henry J. Comley *in medias res*.

he was compelled to put up with variations in the temperature of his developer, simply because the means of keeping a developer at constant temperature were beyond the powers of most photographers in practical work. Therefore it was important that the use of a given factor in summer would give the same degree of density in winter. In his own work he had obtained some similar variations of the factor for the pyro developer; but, remembered right, he did not perhaps in his earlier experiments take all the precautions which he took now to ensure freedom from stain in the negatives. While it was broadly true that the factor did not vary with the plate, it was his experience that an orthochromatic plate required a shorter factor for the same degree of density. He thought that some of the variations in the factors due to the presence of soluble bromide in commercial plates, supposed that plate-makers had a useful purpose in view in including plates containing such soluble constituents, but he thought that the long run it would be found best to avoid anything in a which upset methods of development which assumed the use of a plate free from such disturbing component.

Dr. W. Scheffer said that he had made experiments similar to those of the authors, and he therefore felt very satisfied that they had arrived at the same conclusions as those to which he had come.

## THE ROMANCE OF INSECT LIFE.

[An abstract of a lecture delivered by Mr. Martin Duncan before the Photographic Convention, July 19, 1907.]

VERY early in the earth's history insect life made its appearance, for beautifully preserved insect remains are to be found in those old forests and swamps that have been formed into coal. So in those past geological ages the beetle droned at eventide, and the shrill chirp of the cricket rang through the silent night. In the gloom of those vast primeval forests the spider spread its web from bough to bough. Insects came from out the egg, lived as gormandising grubs, changed to pupæ, and finally burst forth as perfect winged creatures, probably falling victims at various stages of their existence to strange insectivorous reptiles. The battle of life had long begun, and adaptation to environment was fast becoming, if not already, a fixed law in the struggle for existence. During the successive changes which have

insect life has of late years become one of the most important branches of biological investigation, and the results already obtained are of a most startling character, fully demonstrating that these at first sight insignificant creatures are important factors in the life of man. Man is Nature's rebel son, he has set at defiance her authority, and formed for himself a perilous position, which it is impossible for him to maintain, unless he is prepared to seek true knowledge of all those countless forms of animal and vegetable life which swarm around him, and are of vital importance to his well-being, to the survival of his race. The fundamental laws of Nature cannot be lightly set aside or neglected; certain destruction awaits their disregard. It is only by exact knowledge of their life history and environment that man can hope to successfully fight those organisms which have become his foes.

Raising the Status of the Professional.—Messrs. A. Sesman and Alfred Ellis.

The Honorary Lanternist and Mrs. Beard.

passed over the world's surface, insect life has held its own in the battle of life, and to-day insects embody the very principles of vitality, activity, and destruction.

In forest and woodland, and marsh and fen, the insects swarm, fighting, courting, devouring, propagating their species. Away in the lonely North thousands dance in airy winged flight over the frozen sea. They worry the herds of reindeer, driving them ever northward towards the regions of bitter frost. In the tropics they fly far out to sea, where great companies of them will settle upon the rigging and sails of ships.

The study of insect life is full of romance. I do not mean the wearisome examination of endless dead and dried specimens, but the study of the living insect in its natural environment, and of how that environment reacts upon the insect itself. Then, indeed, do we enter a new world, full of wonders, from which we may glean some insight into the laws of Nature which govern life. The study of

This evening I propose that we shall glance at the life of some of those insects with whose general appearance most of us are more or less familiar. We will watch the early life of the dragon-fly, which is passed at the bottom of ponds and lakes. Out in the garden we will follow the bees as they visit the flowers, and gain some insight into their lives, and we will watch the ceaseless labours and wars of the ants and other familiar insects.

The study of insect life is a subject full of interest, and can be made a life-long hobby. If to such labour we can call in the aid of photography, then our observations will increase both in value and interest, for we shall be able to record for all time those characteristics of form and habit which attracted our attention, and which may give us a clearer insight into the true life of these insects. If to-night I can prove to you the value of the application of photography to the study of insect life I shall feel that the many hours and days spent in observation and in obtaining the results I have to show you, have not been spent in vain.

F. MARTIN DUNCAN.

## THE ANNUAL MEETING.

THE annual meeting of the Convention, the decisions of which were briefly reported in our last issue, was held on Wednesday, July 17, in the Town Hall, Hereford, Mr. Alfred Watkins in the chair. The minutes having been read and confirmed, it was proposed by Mr. E. J. Humphrey, and seconded by Mr. F. A. Bridge, that the

invitation of the Association Belge de Photographie for the 1908 meeting to be held in Brussels should be accepted.

Mr. C. H. Bothamley referred to the minutes of the last general meeting, in which it was decided that the Council present a report as to the meeting place for the following year.

The secretary read an extract from the minutes of the Council recommending Brussels as the meeting place, which amounted to a formal report.

Mr. Bothamley thought a formal report should have been presented, but waived his further objection. In reference to the selection of a Continental meeting place, he appreciated as much as anyone the cordiality which prompted the invitation of the Association Belge, but he was of opinion that the holding of a meeting abroad was not in the interests of the Convention. There were many parts of Great Britain in which as yet no meeting had been held. That was the case in the north-west, south-east, in Essex, and in other parts of the United Kingdom. The sea voyage, he also thought, was an obstacle to the holding of a Continental meeting. He also called to mind an invitation which the Convention had received from Paris some years ago. It had been declined, and he thought that the acceptance of an invitation to Belgium was on this latter account also undesirable. He proposed as an amendment that the 1908 meeting of the Convention be held in the United Kingdom.

Mr. A. Horsley Hinton seconded this amendment. At the Council meeting, he said, he had withdrawn his objections in order that the acceptance of the Belgian invitation might be unanimous; but he felt that it was inimical to the future prosperity of the Convention to select a place of meeting outside the United Kingdom.

The Honorary Secretary, in reference to the Paris "invitation," said that it was one of three or four, and, further, was not an official invitation. It amounted to a general suggestion that should the Convention select the year of the Paris Exhibition to meet in the French capital the visit would be welcomed.

Mr. Godfrey Bingley believed that a verbal formal invitation had been presented at a previous Convention.

Mr. S. H. Fry said that the greatest objection to meeting outside

the British Isles was that members who were unable to put in a week at the Convention would be kept away altogether.

Mr. H. Snowden Ward urged that a Continental meeting did not bring the Convention in contact with photographers afterwards became regular Conventioners. He thought, also, the meeting place in a country where a foreign language was spoken tended to create distinctions between members, which it was one of the great objects of the Convention to diminish.

Dr. Thomsen, of Brussels, on being asked to contribute to discussion, said he could say nothing, because, although a member of the Association Belge, he was present in Hereford without the knowledge of that body.

Mr. Harold Baker supported Mr. Bothamley's amendment, which on being put to the meeting, was lost by 22 votes to 25.

On the first resolution being put the voting in favour of Brussels was 35 in favour against 29.

On the proposition of Mr. Snowden Ward, seconded by Tompkins, the thanks of the Convention was accorded to the Municipality of Hereford for the hospitality shown by the municipality. A vote of thanks to the local committee and its secretary, Mr. W. T. Lucas, was proposed by Mr. F. A. Bridge, and seconded by Phipps Lucas.

The auditors (Messrs. Sanger-Shepherd and Schumann) were elected, and votes of condolence were passed in reference to the deaths of Mr. A. L. Henderson and Mr. John Stuart.

#### NEXT YEAR'S PRESIDENT.

At the subsequent Council meeting, Sir E. Cecil Hertslet, Majesty's Consul at Antwerp, was elected to the presidency for the year of the 1908 meeting. It was understood that in the event of his being asked to become President Sir Cecil Hertslet signified his readiness to accept office.

#### THE CONVENTION GROUP AND CONVENTION SNAP-SHOTS.

As promised last week, we give with this issue the key to the group of members of the Convention, which last week we were able to publish in Hereford within little more than twenty-four hours of the exposure being made, through the expedition of the official photographer, Mr. H. J. Unwin, and of the London Studio, by whom the half-tone plate was made. It may perhaps be of interest if we

also reproduce here the photograph by means of which the names of those in the group were obtained. The method needs scarcely a word of explanation. Each of the cards distributed to the sitters bore on the reverse side the request to write the name and address and to hold the card before the face for the special exposure. The photograph is the result of this exposure, and it will be at once

Key Photograph to the Convention Group

understood that the method is not upset by any re-arrangements, but that of exchange of cards after the names have been filled up before exposure. In order to avoid the smaller figures, which had been used if the numbers ran above 99, two series of 99, one with, and one without, stars, were employed, the size of the card being six inches square. In making a key it is almost always necessary to re-number the heads, owing to the unavoidable changing of sitters before exposure, but the infallibility of the key is not affected thereby.

The drawback to the occasional use of the plan is its expense. The making up of the different numbers is not a cheap process, and it is not worth while for one of our trade houses who cater specially to the professional to issue a set of cards, blank on one side and numbered on the other. The cost on an edition of 1,000 only ought to be trifling, and many professionals who have a fair proportion of sitters to photograph would be ready to purchase, not only on account of the labour saved, but for the reason that cards give sitters something to do, and, further, that they imply smartness on the part of the photographer.

A few outdoor hand-camera portraits of the Convention persons which we publish in this issue were nearly all obtained at the President's garden party on the Wednesday afternoon. Light and surroundings were favourable to snap-shot photography, and whatever it survives in the printed reproductions may be ascribed to these factors, for the negatives were exposed by a mere journalist, masquerading as a photographer among a distinguished company of professionals and amateurs. It may be of interest to add that all were obtained in a reflex camera.

#### THE LATE MR. JOHN STUART, OF HELENSBURGH.

At the publication of the few lines last week announcing the death of Mr. John Stuart, of Helensburgh, we have received a portrait of the deceased gentleman, which we reproduce with the melancholy

The late Mr. John Stuart, of Helensburgh.

on that it is the last occasion on which the features of a departed friend are to appear in our pages as a reminder of his active personality. For the short account of the career of Mr. Stuart we are indebted to the "Helensburgh Times."

Born in the city of Glasgow in the year 1831, Mr. Stuart was seventy-six years of age. He served his apprenticeship to the carpentry trade, and married Miss Renfrew, of Glasgow, at an early age. In the year 1851 when photography was little practised in Scotland, an unconquerable desire seized him to acquire this wonderful art. While attending Dr. Taylor's natural philosophy classes in the Andersonian University he became possessed of a rudimentary knowledge of photography, which was subsequently developed during his attendance at the chemistry classes in the same seat of learning. Having gained considerable information on the scientific side of the subject, he proceeded to put it into practice, and with his own hands erected a glass house, made a camera and other apparatus, and set to work as an amateur photographic artist. His first sun pictures of roofs and spires in his native city gave him fresh inspiration, and he pursued his studies with an enthusiasm which speedily achieved success. He retired gradually from his ordinary occupation, and devoted himself exclusively to photography. From a humble beginning he fought his way forward, and by sheer merit and good work his studio in Buchanan Street, Glasgow, came to be regarded as one of the foremost in Scotland. In 1858 Mr. Stuart took up his permanent residence in Helensburgh, where shortly afterwards he opened a branch establishment, and from which, in the course of well-nigh half-a-century, there has emanated such beautiful work. From its origin up till within recent years it was under the management of the late Mr. William Stewart, Giffnock Cottage. Of a singularly active disposition Mr. Stuart throughout his lifetime has taken a keen interest in public affairs, and has proved himself a useful citizen. He was first returned to the Town Council in 1865, and was a member for seventeen years. In 1869 he was created Junior Bailie, and in 1870 Senior Bailie, reaching the top of the municipal tree in 1877, when he was chosen Provost. He held that office for seven years, and during his term was instrumental in introducing many important public improvements.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between July 8 and July 13:—

- PROJECTION APPARATUS.—No. 15,726. Improvements in apparatus for projecting two or three photographic records or colour records. Otto Pfenninger, 105, Hythe Road, Brighton, Sussex.
- REFLEX CAMERAS.—No. 15,774. Improvements in photographic cameras of the reflecting type. Harold Frederick Smith, 33, George Street, Peterborough.
- REFLEX CAMERAS.—No. 15,889. Improvements in folding reflector cameras. William Barton Wood, 322, High Holborn, London.
- CINEMATOGRAPHS.—No. 15,902. Improvements relating to cinematographs and like apparatus. Arcade Mallet, 7, Southampton Buildings, London.
- SHUTTERS.—No. 15,934. Light graduating shutters for use with photographic lenses. Albert Henry Church, 35, Sydney Street, Chelsea, London.
- LENSES.—No. 15,958. Improvements in lenses. Joseph Cook Angus, Birkbeck Bank Chambers, Southampton Buildings, London.
- PANORAMIC CAMERAS.—No. 15,977. Improvements in or relating to means or apparatus suitable for use in observing or photographing objects embraced within the complete horizon. Horace Frederick Denston, 46, Lincoln's Inn Fields, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PLATE HOLDER.—No. 17,179. 1906. The holders are for exposed plates, consisting of a frame furnished with a handle and having one side open and three sides provided with grooves or hooks, so that the plate can only slide out when the frame is inclined towards the hook or handle side and the open side. In manipulating the plate it is only necessary to hold the side of the frame

with the closed groove lower in order to prevent the plate from falling out unintentionally when the open side is placed obliquely. The device serves for holding the plate during all the operations, such as developing, fixing, intensifying, or reducing of the plate. In order to distinguish the holders for placing the plates in the developer from those employed for putting them into the fixing bath, the holders are coloured differently or provided with tangible distinguishing marks. In the figure *C* is the open end of frame, and it must be depressed as regards *g*, the holder, and *C*, so that the plate can slide out. By placing the open ends of two frames together the plate may be made to slide from one

frame to another, if it is thought desirable to use separate frames for separate operations. Carl von Unruh, 18, Moltkestr., Detmold, Germany.

**DARK SLIDES AND CASE.**—No. 24,227. 1906. Fig. 1 shows how the slides are numbered, together with a blank of any suitable material and colour, which acts as a check, arranged consecutively within the case. The slides and the blank which are supported by one

Fig. 1.

or more blocks positioned on the bottom of the case and inclined forward rest between the ribs at the front of the case and one or more springs arranged at the back thereof. When a slide is removed the remaining slides are all given a forward motion, until

Fig. 2.

the slide containing the plate next to be used is automatically placed in position, leaving the space at the back for the slide containing the plate which has been exposed.

Fig. 2 illustrates the construction of the improved slide, which may be of any required dimensions, and constructed of aluminium

having grooves formed by wooden edging, and furnished one end with guide or stop pieces, and at the entrance springs secured to a transverse pin working in bearings set to the base of the slide. At the entrance end of the slide conveniently secured thereto is a lining of cloth or other suitable material, having an outward tendency or springiness. A corner positioned beneath the beaver mole is a flat spring provided, in order that when the slide is loaded with the which rests beneath the guide or stop pieces, and is held firmly in position by the hinged springs which bear on the edges thereof and on the back of the shutter, all possible light entering the slide with its consequent disadvantages while the shutter is removed or replaced is obviated. The of this shutter is bent to protect the outside edges of the slide and any suitable means as a finger piece or a ring may be provided to readily remove and replace the shutter. T. Frederick Caldwell, 81, Neptune Street, Burnley, Melb. Victoria, Australia.

**ROLLABLE FILMS.**—No. 25,188. 1906. This invention relates to rollable films, which are perforated so as to enable the negative to be separated without cutting the roll, and to a means for holding the roll films when one or more negatives have been taken therefrom. Hitherto perforated roll films have been made with perforations in single lines or rows, between each picture space such are difficult to fasten to the backing, owing to the fact that the means for fastening projects over the film and is likely to interfere with the picture.

According to this invention the film is perforated in double rows in such a way that the pictures can be torn off or removed, and when so removed they leave a strip of material which can be utilised for fastening the next following picture to the backing, without interfering with the space required for the picture. By preference a piece of sticking paper or other material is provided, which can be employed to hold the strip to the backing, or the same may be held by clips which hold the narrow strip of material between the two rows of perforations. George Goodchild Stevens and Thomas James Smith, 8, Oswald Street, Rushmore Road, Clapton, London, N.E.

**DAYLIGHT DEVELOPING APPARATUS.**—No. 27,484. 1906. This invention consists of a developing apparatus, formed of two box-like parts jointed together. One of these parts constitutes a dark

Fig. 1.

ing chamber, whereas the other serves as a means for transferring the plate from the dark slide to the developing chamber and back therefrom to a fixing receptacle. Fig. 1 is a cross-section of the apparatus with dark slide applied thereto. Fig. 2 is a longitudinal section through the apparatus opened out

Fig. 2.

the position for transferring the plate from the one part to the other.

The apparatus consists of the two box-like parts, *a* and *b*,

are jointed together at *e* by means of hinges, so that the structure can be doubled up for convenience in carrying. The other ends are not connected to each other. The part *a* constitutes the developing chamber *c*, and comprises also the receptacle *g* for receiving the developing fluid, and contains the ribs *f*, which form stops for the plate.

The developing fluid can, as usual, be let into its receptacle by means of a funnel, and out of the same by an opening provided with a stopper. The bottom and the cover of the chamber *c* consist of ruby-red glass, through which the progress of the development may be observed. Above the ruby-red glass forming the cover of the chamber can be arranged a folding shading device *h*, as shown in Fig. 1, is held folded by the bottom of the part *b*. Beneath the ruby-red glass bottom of the chamber also a protecting slide or the like can be arranged. Carl Friedrich Aurich, Ostra-Allee 17, Dresden, Germany.

## New Trade Names.

**CHROME.**—No. 293,412. Colour-sensitive plates for photographic use. Wratten and Wainwright, Ltd., 76, Canterbury Road, Croydon, Surrey; photographic material manufacturers. June 1, 1907.

**CHROME.**—No. 293,413. Colour-sensitive plates for photographic use. Wratten and Wainwright, Ltd., 76, Canterbury Road, Croydon, Surrey; photographic material manufacturers. June 1, 1907.

**AGLOSS.**—No. 293,812. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. The firm of Nobles and Hoare, 3, Cornwall Road, Stamford Street, London, S.E.; varnish and japan manufacturers. June 14, 1907.

**AMATTE.**—No. 293,813. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. The firm of Nobles and Hoare, 3, Cornwall Road, Stamford Street, London, S.E.; varnish and japan manufacturers. June 14, 1907.

**TYPE.**—No. 293,063. Photographic paper. Rheinische Emulsions-Papier Fabrik Actiengesellschaft (a corporation organised under German law), 3, Gasanstaltstrasse, Dresden-Reick, Germany; photographic paper makers. May 16, 1907. Address for service in the United Kingdom is, c/o Herbert Haddan and Co., 31 and 32, Bedford Street, Strand, London, W.C.

**LO.**—No. 293,068. Photographic printing papers. Otto Fulton, Fellow of the Royal Photographic Society, African House, High Road, Chiswick, Middlesex, W.; manufacturer. May 17, 1907.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Press Users of Reflex Cameras

While on the subject of reflector cameras (says "Photography") might refer to a discussion which has been taking place lately whether this type is the most suitable for advanced work or those who hold that it is not have referred in support of their to prominent medal winners, who are not users of reflector cameras. Unfortunately for the force of the contention, "advanced" camera work is not defined. Medal winning at exhibitions has nothing whatever to do with it. The exhibitors named would be very first to disclaim the fact that their successes were technical triumphs, or that their work imposed any great demand upon their cameras. The most advanced—that is to say, the most difficult technology—hand-camera work that is done at the present time does figure in exhibitions at all, which are almost exclusively devoted to pictorial photography, a branch which makes fewer technical demands than any. It is the press photographer who wants the most perfect apparatus, and who tries its capabilities to the utmost; and it is no exaggeration, but bare fact, to say that the press photographer who does not use a reflex camera does not.

At a big race meeting a few weeks back we noticed over a press photographers busy in recording scenes on the course in the stands and paddock, and every one, without exception, a reflex camera.

## The Oil Printing Process.

To shorten the bristles of a brush (writes Mr. Stanley Saunders in "The Amateur Photographer") or to shape them like a deer's foot, as recommended by M. Demachy, soak the bristles in strong glue or size, and then set aside to dry, taking care that all the bristles are straight. When hard, cut nearly to the length or shape required, and then grind the rest down on a grindstone, first wiping the loose dust off the stone. If the hairs tend to fray out whilst grinding, bind them round tightly with string. When finished, soak well in water to remove the glue. The brush will be slightly softened by this dodge.

## New Books.

"Theoretisch-praktisches Handbuch der Photographischen Chemie." By Professor R. Namias. Pp. 406. 8½ x 5½. (Halle: Wilhelm Knapp 8s.)

This is a German translation, by A. Valerio and Dr. C. Sturenburg, of the third Italian edition of Dr. Namias' well-known work. It is a clearly written exposition of the various chemical processes which occur in photography from the standpoint of the older chemistry, that is to say, the old school which was content to give everything its chemical equation, no matter how complex the reaction might be. The newer physical chemistry is not touched at all. It is an extremely readable work, sketching in with somewhat light touch every process, and throughout the information will be found to be generally satisfactory. We note, however, that when dealing with the sensitometry of plates there is no mention of the Hurter and Driffield system. The chapter devoted to orthochromatic work has been brought up to date by the inclusion of the newer isocyanine dyes, but with no mention of the filter yellow K.

"Annuaire Général et International de la Photographie." 500 pp. and 225 supplement. Paris: Plon, Nourrit et Cie. Five francs.

The sixteenth yearly issue of the "Annuaire" again appears, under the editorship of M. Roger Aubry, in whose hands the volume preserves its accustomed features. Intended for the amateur and student of photography, its pages are chiefly devoted to a review of progress in the optics, chemistry, and technics of photography during the past year, in which section we find also a chapter on "The Scientific Applications of the Camera to Stereoscopy, etc.," one on "Colour Photography," and still another on "New Items of Apparatus." Among the other literary contents is a fully illustrated article on "The Methods of the Maker of Trick Cinematograph Films." The volume includes the indispensable tables and formulæ, and contains also a directory of French amateur photographers, classified under the societies of which they are members.

"THE PHOTO-MINIATURE."—No. 79 of our excellent New York contemporary (London: Dawbarn and Ward, 6d.) deals with the choice and use of photographic lenses, and contrives, even on this well-worn topic, to say some things in a different way, and to make still clearer some of the points which are difficult of comprehension by the beginner. It is, in fact, a book of lens small talk—without equations, without even a single diagram to bear an aberration company. Editor Tennant is greatly to be congratulated no less than his readers.

"FINISHING THE NEGATIVE."—Messrs. Dawbarn and Ward, in issuing a new edition of this handbook of the after processes which a negative may require, have made it uniform with their popular shilling series of books, of which the excellent "Figures, Facts, and Formulæ" is a fairly representative volume. Brought down from the lordly price of half-a-crown (nett), the new issue suffers only in the matter of cover and paper. The latter is a minor matter, as the half-tone illustrations are placed on art paper. The book is very much more than a collection of formulæ; it contains a good deal on manipulation and principles, and in its shilling form, revised by Mr. Snowden Ward, it should prove a most useful shelf companion to any practical photographer.

THE ANNUAL EXHIBITION of the Hackney Photographic Society will be held on November 6, 7, 8, and 9.

## New Apparatus, &c.

The "Standa" Daylight Time-Development Tank. Made by The Standard Patents Co., Ltd., 11, Bond Court, Walbrook, London, E.C.

A new and improved model of this tank, which has now been before the public for several years, has been introduced by the makers. The original pattern of the tank embodied a number of conveniences in a surprisingly small space, a feature of the apparatus which has been very generally appreciated, we think, and has, in fact, done much to dispose photographers in favour of the stand method, inasmuch as the "Standa" is very economical of developer. The tank still consists of an inner and outer vessel, the latter holding the developer, and the former, loaded with plates, being lowered into it and admitting the developer at the bottom. In the tank before us the inner vessel holds six quarter-plates. The outer one is charged with seventeen ounces of developer, which, when made up from the powders supplied by the firm, will develop to good density in five minutes, or a developer to act completely in a longer period can easily be prepared by making a weaker solution. Whichever be the solution adopted, the "Standa" tank, as we have found in an experience of it which commenced on its first appearance, is a most handy apparatus in use. If one is not content, as we confess we are not, to develop invariably by time, the plates are very easily removed by raising the inner tank and withdrawing any particular one from its grooves. Others will prefer to adopt the daylight method and secure the comfort of working in daylight (and fresh air), and in this respect we have found the tank quite efficient.

Still it is none the worse, but in our opinion, all the better for its ready application to dark-room use. From its compact size and ease of cleansing, the tank is just as well suited to tourist purposes as to regular work in a professional establishment, in which latter respect a good word must be said for the way in which the metal of which it is composed resists corrosion if washed after use. The Standard Patents Co. have recently brought out tanks for two exposures only to meet the wants of those taking their photography in small doses. Particulars of these, as of all the sizes in which the apparatus is made, can be obtained from any dealer, or from the firm at the address given above.

MESSRS. J. H. DALLMEYER, LTD., who have recently removed their factory to larger premises at Neasden, held their annual beanfeast on Saturday, the 19th inst. Fine weather favoured the occasion, enabling some of the party to make the trip by steamer down the Thames. After dining at Murray's Hoy Hotel excursions were made by tram and boat, the return journey being effected by a late train.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY. — The multitude who take an interest in photography will find a capital exhibition now in progress in the East Gallery of the Alexandra Palace. It is made up of photographs by members of the North Middlesex Photographic Society, which has been in existence for nineteen years, its object being to extend the study of the art. In all there are 176 exhibits, embracing a variety of subjects, the rural being particularly prominent. Much-prized landmarks, castles, ancient gateways, etc., provide some very interesting specimens, whilst woodland stretches, visions of picturesque hill and dale, and the glories of life by lake and river add welcome contributions to the list.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK

SATURDAY, JULY 27.

Hackney Photographic Society. Outing to Winchmore Hill Woods.  
Rugby Photographic Society. Outing to Althorpe.  
Devonport Camera Club. Outing to Mount Edgcumbe.  
Edmonton and District Photographic Society. Outing to Waltham.  
Borough Polytechnic Photographic Society. Outing on River Thames.  
Coventry Photographic Club. Outing to Astley and Arbury.  
Aberdeen Photo Art Club. Outing to Loch of Park.  
Manchester Amateur Photographic Society. Outing to Prestwich.

SUNDAY, JULY 28.

North London Photographic Society. Outing to Denham.

TUESDAY, JULY 30.

Hackney Photographic Society. Members' Open Night.

WEDNESDAY, JULY 31.

Leeds Camera Club. "The Dark Room, its Arrangement, &c." John Le  
United Stereoscopic Society. "Micro-Stereoscopy Without a Micro-  
G. W. Stannard.

## Commercial & Legal Intelligence

PHOTOGRAPHING PLANS.—The London Stereoscopic and graphic Company, Ltd., of Cheapside, sued Charles Wall, Ltd. way contractors, of Lloyd's Avenue, at the Lord Mayor's Court July 15, for £65 14s. for work done. Mr. B. Lailey (instructed by Mr. Cox) was counsel for the plaintiffs and Mr. W. G. Glynn (instructed by Messrs. W. Carpenter and Sons) for the defence. Mr. J. L. Mitchell, general manager and secretary to the company, said that on January 11, 1906, the order was given for the name of the defendant firm being entered in the books. Miles, manager of the plaintiffs' Cheapside branch, stated that fortnight after the invoice was sent defendants asked that it be made out to the British Contract Corporation. That, he said, the plaintiffs declined to do, as the order had been placed with in the name of the defendants. For the defence Mr. H. W. Waite, who said that the defendants had never given any authority to the person whose instructions were followed to act for them. The parties to them on being opened was delivered to the adjoining office of occupation of the gentleman in question. The jury stopped at the close of the evidence, and returned a verdict for the plaintiffs for the amount claimed.

"FOR CASH ONLY."—The Rotary Photographic Company, 1 Union Street, Moorfields, sued Messrs. Daniel Bros., of Morley, Leeds, at the Greenwich County Court last week, for £21 10s. sold. To satisfy the action, which had been remitted to the High Court, defendants had paid £14 6s. 11d. into court. H. B. Sewell was for the plaintiff, and Mr. C. H. Dodd for the defendants.—The cause of the dispute between the two parties was to whether the defendants were entitled to a certain discount which plaintiffs refused to allow, on the ground that it was a cash discount only.—His Honour took this view, and found for the plaintiff, with costs.

EARLY MORNING PHOTOGRAPHERS.—Walter Knight, 18, of Albert Street, Portland Town, and George Hurrell, 18, of Little Street, Camden Town, were charged at Marylebone Police Court last week, with breaking and entering 256, Finchley Road, stealing 15s., two syringes, a camera, rubber stamp, six keys, and other things, worth £2 2s., the property of J. H. Lewis, chemist. Police-constable Young, 256 S, said he was in Marylebone Gardens about half-past one o'clock that morning, and saw the defendants loitering about suspiciously. Knight was carrying a camera in his hand, and when questioned about it he said it belonged to him. He had been up to Hampstead Heath taking photographs, being satisfied with the explanation, the witness arrested the pair. At the station a number of keys were found on the men, and the prosecutor's address was on one of them inquiries were made of Detective-sergeant Loder, and it was found that the premises had been broken into, the glass of a window being broken, thus giving access to the shop. All the missing property was found on the prisoners. Mr. Paul Taylor sent the case for trial.

**PHOTOGRAPHIC FRAUDS.**—At the Liverpool Assizes, last week, Thomas and William M'Hugh, father and son respectively, were found guilty of what the Judge termed a cruel swindle, and sentenced Thomas M'Hugh to twelve and William to nine months' imprisonment. The men induced persons to part with considerable sums as premiums to learn the photographic business, the younger man having a studio.

**SUNDAY TRADING.**—At the Grimsby Police Court, on July 19, John Hawkey, photographer, was charged with trading on June 23, 30, and July 7. According to the police evidence, Hawkey was standing outside his studio inviting people inside, and he several times went into the studio. Hawkey was called by Mr. Wainwright, who defended. During the week, he said, he carried on business as a photographer, but on Sundays he had nothing to do with the business except standing outside and telling people the price. His wife did all the photographing, and all the money taken was hers absolutely. Mr. Wainwright submitted that the Act could not have contemplated photography, as it had not been invented when the Act was passed—and he mentioned that the Act was so ancient that if the fine was not paid a man could be placed in the stocks for two hours. He contended that Hawkey was not a tradesman. The King's Bench had decided that a tradesman was one who bought and sold goods. When a photographer charged for the photographs he did not charge for the materials, but films, time, and skill in taking the photograph, in the same way as a barber charged for shaves, and a barber had been expressly held to be exempted under the Act. Another point was that the business on a Sunday was not carried on by the defendant, but by his wife. The defendant did this, he did not mind admitting, with a view to getting out of the Act, and it had therefore been done completely, the business being absolutely transferred to the wife. The defendant did not take part in the business, and did not receive a penny of the money taken on Sundays. He mentioned that other Benches had taken different views of this question. At Blackpool the Bench refused to convict photographers. Another Bench also refused because they said Sunday was the only day in which a working man could get photographed in his best clothes. The Bench found that the defendant took part in the business, and that his wife carried on the business for her husband. On those grounds they convicted him. A fine of 5s. and 5s. 6d. costs was imposed in each case.

#### NEW COMPANIES.

**EDWARD WATSON AND CO., LTD.**—Registered July 15. Capital 1,000, in £1 shares. Objects: To take over the business of chemists, druggists, drug and patent medicine vendors, dealers in pharmaceutical, medical, chemical, optical, surgical, photographic, and other reparations and apparatus carried on by E. Watson, at 100, Mitcham Road, Tooting, as Watson and Co. No initial public issue. Registered without articles of association.

**PARKER AND KNIGHT.**—July 12. £500 (£1). To acquire the business carried on by J. W. Parker, and to carry on the business of photographers, etc. No initial public issue. Registered without articles. 108, Clarendon Road, Southsea. (94,159.)

## News and Notes.

**MR. CHARLES E. SPEIGHT**, the well-known photographer, of London Road, Kettering, was married on the 16th inst. to Miss Florence L. Collings, eldest daughter of Mr. Edward Collings, of the Royal Hotel, Kettering.

**NORTHAMPTON NATURAL HISTORY SOCIETY** (Photographic Section).—On July 13 some dozen members of the photographic section of the Northamptonshire Natural History Society went to Rugby with Mr. R. G. Scriven, J.P., as their leader. At Rugby they were met by Mr. R. H. Myers, the honorary secretary of the Rugby society, and after a short stroll round the town, were met at the schools by the president of the society, Mr. B. B. Dickinson, M.A., who conducted them over the buildings, and through the chapel, gymnasium, workshops, library, and museum. The party also visited the churches of St. Andrew and Holy Trinity, and partook of tea in the St. Matthew's parish buildings. After the meal Mr. Myers expressed, on behalf of Mr. Dickinson, the Rugby society's welcome to the Northamptonians. A vote of thanks to the Rugby friends was proposed by Councillor J. J. Wetherell (vice-president of the section), and seconded by Mr. C. H. Dorman (hon. secretary).

**"FINGER-PRINT PHOTOGRAPHY."**—Mr. Oliver Cromwell, a detective and photographer in the Bradford City Police, has published, with Mr. Elliott Stock, an intelligent little book on the above subject, a branch of photography which would appear to be of considerable value in the detection of crime. It is believed that the markings on anyone's fingers never change, and that no two persons have ever been found to have the same markings, and it is therefore claimed that this finger-print science should give irrefutable proof as to the guilt or innocence of a suspected person. With this end in view it is to be hoped that Mr. Cromwell's little book will be largely studied by members of the police force, and stimulate many of them to take an interest in the subject with which it deals.

**"TOURIST GUIDE TO THE CONTINENT."**—A new edition of this popular guide has just been issued by the Great Eastern Railway, and includes among its special features particulars of a number of new tours in various districts, including the Hartz and Thuringian mountains, the lesser known valleys of the Rhine, some of the old Flemish cities, etc. The book is well illustrated, and contains a practical feature in the form of a series of Continental maps. Copies may be obtained from the publishers, 30, Fleet Street, E.C., and 12a, Regent Street, W.; from the Continental Department at Liverpool Street Station; or may be ordered from all booksellers and railway stations. The price is 6d.

**ANNUAL OUTING OF HOUGHTONS, LTD.**—On July 13 the warehouse and office staffs of Houghtons, Ltd., had their annual outing. Starting from Waterloo at 10 o'clock they travelled to Staines by train and then embarked on the launch "England," and as the weather was fine a really enjoyable day was spent. Lunch and tea were served on board in the saloon of the boat, Mr. George Houghton, senior, presiding at the first lunch, and Mr. Edgar Houghton at the second. The boat went as far as Bray Lock, and on the return journey stopped at Windsor for an hour, thus affording an opportunity for a visit to the castle. The homeward trip was particularly enjoyable, and the party landed at Staines at 8 o'clock. About 200 members of the staff were on board. The "Ensign" Works outing took place on the week previous.

**THE "TICKA" BOOKLET.**—A booklet, giving full particulars and price list of the "Ticka" camera and accessories, has been issued by the makers, Messrs. Houghtons, Ltd., of 88 and 89, High Holborn, London, W.C. It contains numerous illustrations showing the kind of work that may be done with this little instrument, and the results obtainable, both when printed from the film in direct contact in the ordinary way and also when enlarged in the "Ticka" printing-box. A series of specimen prints, taken by an amateur, is also included in the booklet, and Messrs. Houghtons will be pleased to send a copy of both to any of our readers who have not already purchased a "Ticka," or applied for particulars, on their mentioning the "British Journal" in their application.

**VELOX COMPETITION.**—The following are prize-winners in Messrs. Griffin's monthly "Velox" competition:—First prize (2 guineas), H. Beetham (Nelson, Lancs.); second prize (1 guinea), David Bain (Glasgow). Twelve prizes of 5s. each were also awarded to Thomas Marshall (London), J. H. Williams (Kettering), H. W. Hillier (Maidstone), E. J. Brooking (Wisbech), W. Muff (Hipperholme), E. P. Grigg (West Bromwich), A. Vernon Wilkinson (Birmingham), Mrs. Helen Mackinnan (Aberdeen), Miss N. Mercer Adam (Bath), William Duff (Glasgow), Mrs. Myles (Clifton, Bristol), and W. E. Cork (Nelson, Lancs.). As this competition is strictly for those who have never won a prize before, the above prize-winners are debarred from again competing, and the opportunities for beginners thereby increased.

**THE ROYAL PHOTOGRAPHIC SOCIETY'S** annual dinner is announced to take place as soon as possible after the close of the exhibition. Messrs. A. W. W. Bartlett and Leslie E. Clift have been appointed joint honorary secretaries, and members of the Council will act as stewards, whilst it is hoped that all members of the society will assist in making the function a success. Tickets, which will be issued later, will be 7s. 6d. each.

**ROYAL PHOTOGRAPHIC SOCIETY.**—On Tuesday, October 8, at the New Gallery, 121, Regent Street, W., Mr. J. C. S. Mummery, A.R.I.B.A., F.R.P.S., will deliver the annual presidential address on "The Position of Pictorial Photography."

**MR. DRINKWATER BUTT**, F.R.P.S., has removed from his late address in St. Stephen's Avenue to No. 24, Queen Street, Hammer-smith, where he will have greater facilities in carrying on the various

branches of his work, among which he is at present giving much attention to the designing and fitting up of studios, both artistic and photographic, work now in hand including a painting studio, to be erected at Cropthorne, Worcestershire, for the well-known landscape artist, Mr. T. Hodgson Liddell, R.B.A.

**PHOSPHORESCENT PAPER.**—Relative to an inquiry in our columns last week respecting phosphorescent paper, a correspondent informs us that this is manufactured by, and may be obtained from, Messrs. Horne and Sons, Ltd., City Road, E.C.

**MICROSCOPY OF THE PLATE GRAIN.**—In reproducing the photomicrographs of Dr. Scheffer last week the inversion of one photograph showing the grain of the plate before and after mercurial intensification disguised the fact that both photomicrographs showed precisely the same portion of the subject. We insert again these two blocks,

Fig. 19.—Before mercurial intensification.

Fig. 20.—After mercurial intensification.

with Fig. 20 inverted, in order to show, from the right-angled formation near the centre of the circle that the same portion of the subject is included in each case. If with the blocks in this position the description on page 543 of our last issue be re-read, the points indicated by Dr. Scheffer can be more easily followed.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### STAND DEVELOPMENT, AND A CORRECTION.

To the Editors.

Gentlemen,—Mr. Washam's tank, as he describes it in your issue of the 19th inst., would appear to be a very convenient form, especially as he requires the simultaneous development of various sizes. Personally, I use porcelain dipping-baths, as made for wet-plate work. For instance, I have three or four 10 x 8 baths (i.e., taking 10 x 8 plates), these take two half-plates each on the one dipper, or eight half-plates for the four; larger sizes are developed singly. Glass dippers I eschew, as sooner or later, and generally the former, the bend at the bottom of the dipper becomes broken off by striking against the bottom of the bath, when the dipper is rendered useless. I make my own dippers out of stout copper wire, having a width between the legs of about four inches. Before the feet are turned up to rest the plate upon a piece of hard wood or vulcanite, with holes four inches apart, is slid on to the dipper, and being of about  $\frac{1}{4}$  in. to  $\frac{3}{8}$  in. in width, it forms a rest for the second plate. When the dipper is wanted for, say, 9 x 6 plate, the ledge is pushed up to top of dipper out of the way. I usually silver my dippers before taking them into use, but possibly this is an unnecessary refinement.

I find an error was allowed to pass when correcting proof of the article. "The bath of bisulphite recommended for clearing between development and fixation is given in my paper as 1 per cent., this should be 10 per cent. (ten per cent.).—I am, Gentlemen, yours faithfully,

Sidmouth, S. Devon.

G. T. HARRIS.

### STAND DEVELOPMENT.

To the Editors.

Gentlemen,—In the correspondence section in the "B.J." current issue, we notice a letter upon "Stand Development" from Mr. W. Washam, Lausanne, wherein he refers to tanks for this method of

developing, and states: "I have seen lately, perhaps in the "B.J." something of this kind noticed, but on inquiry I found it to be for the English  $\frac{1}{4}$ -plate size only." We surmise he refers to our "Mérito" developing tank, and beg to advise you if he had only made the inquiry direct to ourselves, as the patentees, we should have been able to tell him that we have other sizes—namely,  $\frac{1}{4}$ -plate 5 x 4, P.C.,  $\frac{1}{4}$ -plate, and 1-1-plate, and, in addition, we can make any size to order. We can only surmise he has applied to some other firm in the trade, who have evidently considered it too much trouble to ascertain. Therefore, we shall be much obliged if you will inform your readers that we have the sizes in general use now upon the market, to take both twelve and six plates at the following prices:—Tanks to hold twelve  $\frac{1}{4}$ -plates, 5s.; 5 x 4 and P.C., 6s. 6d.  $\frac{1}{4}$ -plate, 7s. 6d. Tanks to hold six,  $\frac{1}{4}$ -plate, 3s.; 5 x 4 and P.C. 4s. 6d.;  $\frac{1}{4}$ -plate, 5s. 6d. In addition, loose carriers can be supplied with any of the tanks to take smaller-size plates than the size mentioned, so that one tank can be used for various sizes, but we only supply these carriers to order.—Yours truly (for W. L. Parkinson, Ltd.),

W. L. PARKINSON.

5, Commutation Row, Liverpool.

### THE SULPHOCYANIDE-PERSULPHATE REDUCER.

To the Editors.

Gentlemen,—I see by the report in this week's "B.J." (page 544) that Dr. Scheffer, in his address to the Convention, said:—"Late Mr. Dr. Lüppo-Cramer has found that if we add sulphocyanide of ammonia, or a similar acting substance, to the persulphate of ammonia, this works exactly like Farmer's reducer." I thought I would drop you a line to mention that I found out this fact and published it in "Photography" over seven years ago ("Photography," February 8, 1900, pages 86 and 99). The combination referred to makes an excellent reducer, and has the advantage over ferricyanide and hypo in that it does not cause stains. Mr. W. H. Alexander, in an article on "Reducers" in "Photography" for April 2 last, page 289, after referring to several other reducers which act similarly to ferricyanide and hypo, says:—"But the one which has succeeded best in the writer's hands is one due to Mr. S. C. Puddy, and consists of a mixture of ammonium persulphate and ammonium sulphocyanide," etc.—Yours faithfully,

S. C. PUDDY.

Arrington House, 87, Crouch Hill, N., July 22, 1907.

### HYDROQUINONE AND GLASS.

To the Editors.

Gentlemen,—The group of diacidphenols, of which hydroquinone is a member, are all more or less affected by the action of light. In the case of hydroquinone this action results in a perceptible darkening of the reagent and some loss of developing power. Consequently manufacturers and wholesalers usually stock this chemical in the dark, either by putting it in a stone jar, or, if in a glass bottle, by enclosing it in a carton or some similar device.

My own experience tends to show that with the very pure hydroquinones now on the market this action goes on very slowly, and although I usually keep the chemical in a jar as a safeguard against breakage, I should have no hesitation about putting it in a bottle. In fact, I have done so upon several occasions; but I have always taken care to keep the bottle away from anything like strong sunlight. Possibly the manufacturer who sent out the packages mentioned in your note last week was under the impression that although a pound of hydroquinone might darken before it was used, an ounce would be more likely to be used before the light affected it. If this was not his idea (and perhaps if it was) he should have either sent out the bottle in a carton; or put the chemical in a dark non-actinic bottle. Wrapping in paper is a poor way out of the difficulty, and rather savours of slovenliness. At any rate, I think photographers or dealers need fear no trouble arising from the storage of hydroquinone in bottles and under ordinary indoor conditions, providing it is not kept in stock more than a few months, and also, as I said before, that the chemical is fairly pure.—Yours very sincerely,

ANTHONY J. PRESTON.

37, Grove Lane, Camberwell, S.E.

### A POINT IN COMMERCIAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—The article in this week's "B.J." on "The Ownership of Negatives" brought to my recollection a curious condition made by a customer who asked me to supply negatives of a number of local views. His stipulations were:—That the views must be

original, and (here is the point) that I must on no account make a negative for my own use should I make more than one of any of the subjects. I came to an arrangement with but since then I have often wondered if such a restriction be enforced.

When I am asked to make a negative of a particular street and after making an exposure for my customer I then make myself am I, in so doing, guilty of breach of good faith? continual movement and changes in the grouping of figures make the negatives distinct from one another. Yet, by reason of having been taken during a period of time for which the photographer would be charged, would I, on that account, be justified in other than giving my undivided attention to his order? In words, to take views for myself while engaged in executing a customer's order would appear almost the same as for a printer to print during the hours for which he is paid by his customer. I should be glad if you would kindly express your views, and I am, yours faithfully,

D. A. GRANT (Manager).

The point raised by our correspondent is an interesting one, and it is comment on it would, of course, be a case in the courts. However, of none, however, which applies in the precise circumstances above referred to. In our judgment, a photographer who, in executing for a customer a commission which is supposed to give the customer the sole right in a photograph of a particular scene, is not within his right in there and then making negatives of the scene which differ only in such minor matters as focus, etc. It is perfectly true that the terms of the Copyright Act prevent his creating several copyrights, yet there can be no doubt as to the light in which a judge would regard his action, such a case come before him. We shall be glad to hear the views of other photographers on the subject.—Eds. "B.J."]

## Answers to Correspondents.

Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given. Communications relating to Advertisements and general business should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. An unmounted copy of each photograph must be sent with the registration.

### PHOTOGRAPHS REGISTERED:—

Portrait, 12, Albany Road, Cardiff. Photograph of the Lord Mayor of London, 1907. Race: Finish with Leander Boat Club and Belgium Crew, 5, Bold Street, Liverpool. Photograph of the George's Basin, London, 7, Castle Street, Thetford, Norfolk. Photograph of Stone Coffin found at Thetford Gas Works. Three Photographs:—Henley Regatta, 31, Hart Street, Henley-on-Thames. Race: Finish with Leander Boat Club and Belgium Crew, 5, Bold Street, Liverpool. Photograph of the George's Basin, London, 7, Castle Street, Thetford, Norfolk. Photograph of Stone Coffin found at Thetford Gas Works. Two Photographs (both groups) of Dr. W. G. Grace and Mr. and Mrs. A. B. Crosby. Two Photographs of Geo. Butterfield. Two Photographs of Dr. W. G. Grace. Two Photographs of Dr. W. G. Grace with Mr. A. B. Crosby. Photograph of the Father Bernard Vaughan, S.J., Photograph of the Lord Abbot of Westminster and the Rev. Dr. Graham, Bishop of Plymouth. Photograph of the Wellingborough Volunteer Band.

DEVELOPMENT.—In your issue for July 5 you publish an article "Tank Development," by C. H. Claudy. In giving formulae for the chemicals should be fresh and dry. Are we to understand by that that both the sodium sulphite and sodium carbonate are to be anhydrous?—L. C.

es, we take it that both salts would be of the anhydrous form. We divided the salts are in good condition—that is, pure, and not reduced—there is no necessity to use the anhydrous form, and

you could use 162 grains of ordinary carbonate and 180 grains of ordinary sulphite.

EMBOSSING PHOTOGRAPHS.—I should be under a great obligation to you if you would let me know the easiest and cheapest way of embossing photographs.—H. S. C.

By one of the embossing presses, obtainable from any large house of supplies.

TONING BROMIDES.—Will you kindly let me know the best way of toning bromide postcards to brown colour, in fairly large quantities? I think it is the sulphide process I want, but I am not familiar with the methods. Would the cards be permanent?—K. R.

The sulphide method is described on p. 523 of our issue for July 12. Another method is to use the hypo alum bath, given on p. 988.

VIEW FINDER, ETC.—I have an ordinary field camera, whole-plate, fitted with Busch anastigmat lens,  $f/5.5$ , 10in. focus. I wish occasionally to use same as a hand camera for press work—sporting events, etc. I purpose using a strap round neck to support camera. I should be glad to know what view finder you recommend. Also any hints re focussing scale would be appreciated. I have always been used to focus on ground glass.—NELSON.

If the camera is hung round the neck it would be impossible to use any form of finder but the usual miniature camera or brilliant view finder in which the image is seen on the top. With regard to the focussing scale, this could be made either by setting up the camera on a tripod and focussing objects at known distances and marking the baseboard, and this is the most practical method, or it must be calculated out. The first thing to do is to find the infinity mark, which can be easily done by focussing the clouds or the moon. Then  $x = f^2/d$ , or, in words, the square of the focus divided by the distance will give the necessary extension of the camera beyond the infinity mark. Suppose, in the case in point, it is required to find the extension for an object forty feet away, then  $10 \times 10 \div 480 = .21$  inches, the extra extension required. This does not take into account the depth of focus; this would have to be calculated for each stop.

LENS.—We certainly should not advise the shorter focus lens, but you could obtain one of the same focus by paying a little extra money. It is perfectly immaterial what lens you get, as you cannot obtain more depth of focus with the same focus and same aperture. If you focus for the middle row you probably would not have to stop down so much, as then you use the front and back depth of focus. You would probably find the anastigmat give you a sharper picture at the larger aperture than the other lens, because it is better corrected.

COPYRIGHT.—Would you kindly give me your opinion on the following? If C. gets a photograph from me (copyright mine), without permission to reproduce and without paying me for same, copies it, and forwards to magazine, etc., and they are reproduced under the name of C., who gets the fee for reproduction, as the work is presumed to be his? What remedy have I, and what is the best course to take? Or, presuming that, instead of making a copy of mine, he sends it (the original) along, and it is reproduced under his name, is the infringement against my copyright with him or the paper that reproduces? Trusting the above is clear, as I find one paper last week has reproduced my copyright photograph, and another paper has had a block made, but not yet published same.—CRAYON.

It makes no difference as to the infringement by a newspaper, whether the block was made from a copy or your original photograph. In either case it is an infringement of your copyright, and if you have registered your copyright you can take action through your solicitor. We should advise you, however, to first point out the facts to the newspapers and ask them what they propose doing, to settle the matter amicably. In the event of the photograph not having been registered, you have no remedy, but you can register at once and stop further infringement.

STAND DEVELOPMENT.—(1) A good formula for studio negatives, to be developed by the "stand" method, and printed on platinum. Do you think diamidophenol would be good? Naturally, I want to obtain the best results, but at the same time be economical.

(2) Do you think a wooden tank detrimental? (3) How can I avoid blisters on P.O.P. matte? I work both glossy and matte in one bath. The former does not blister, but the latter is very often covered with them. The usual gold and sulphocyanide bath used.—**EN AVANT.**

(1) See July 5, p. 503, and July 12, p. 521. Diamidophenol can, of course, be used, but we cannot see how this is going to be more economical than any other developer. One of the most satisfactory developers is glycine, according to Von Hübl's formula:—

Boiling water .....	4 ozs.
Sodium sulphite .....	2½ ozs.
When dissolved add—	
Glycine .....	1 oz.
and then in small quantities—	
Potass. carbonate .....	5 ozs.

This forms a thick cream, which must be well shaken and diluted with 80 to 90 parts of water, with the addition of 1-10 grain of potass bromide per ounce. This takes some hours, but reduction of the water naturally reduces the total time of development. (2) We should prefer a well-made metal tank, such as the "Standa" or Reynolds and Branson's. (3) Look to the temperature of the solutions, and immerse the prints, after fixing in a 10 per cent. solution of formalin, or, if the blisters appear before fixing, use the formalin before toning.

**COPYRIGHT.**—(1) The procedure to be adopted when it is desired to copyright a photograph or negative, the fee, and address of the office? (2) Does the copyright, if a photograph, cover its negative, and has each print to be marked copyright? (3) In the event of there being no copyright in a photograph or negative, is any person or firm authorised to make use of the same on their obtaining a sample of the same by any means? From the Copyright Act, p. 1074 of the "B.J.P. Almanac" of this year, it would appear this is permissible. (4) Suppose a photographer takes a photograph of a person and receives payment for the same, and in the event of the latter not assigning the copyright to the former in writing at the time, to whom does the copyright belong? From the latter portion of Par. I. of the Act, it would appear to belong to neither of them. Further, from the former, and from the last portion of Par. IV., p. 1075, of the "B.J.P. Almanac," that under these circumstances, which is quite conceivably a common occurrence, it appears that both are at perfect liberty to use and reproduce the photographs in any way or form they wish, provided no copyright is registered at the time or subsequently, and provided the latter has not retained the same at the time of the photograph being taken. I may, of course, be quite wrong in my interpretation of the Act, as I am unversed in legal matters, but this is how it reads to my mind, and would be so read, I think, by anyone not so versed. (5) Suppose the right of reproduction of a photograph in any particular form is sold to a firm of printers or publishers for so producing, and a percentage on the output is to be paid by the latter to the former, what check is there that the amount they credit corresponds to the actual number of productions they print or publish, say, for instance, in the case of a postcard firm? (6) Same as No. 1, but with reference to patenting anything in the photographic line? (7) If you can give the address of any reliable patent agents, etc., who undertake to do this at moderate rates? (8) In a patented article, who looks after, and is responsible for, the patent rights—i.e., that the article is not used by others; or, if so, that the correct royalty or other charge is credited to the patentee?—**QUERIST.**

(1) The full procedure is given in the "Almanac," 1906, p. 665. A print must be deposited at Stationers' Hall, London, E.C., a fee of 1s. paid, and a form filled up, giving a description of the print, the name and address of the proprietor of the copyright, and of the author of the work. This is signed by the proprietor. (2) It does. The prints need not be marked copyright. (3) Certainly, it is permissible. (4) To the sitter, who pays for it. You are mistaken in your reading of the Act. See the article in the 1906 "Almanac." (5) None, except the right to examine their books. (6) Apply to the Patent Office, 25, Southampton Buildings, Chancery Lane, E.C. (7) Rayner and Co., 37, Chancery Lane, London, W.C. (8) The manufacturer usually is interested in detecting infringements, and equally a

patentee, who is collecting royalties. There is no office on the payment of royalties.

**ARC LIGHT PHOTOGRAPHS.**—Will you please be good enough to tell me the cause and preventive, if any? The movements are practically identical, and they all go one way. I wind any effect on them, as it was in that quarter? If I get the arcs without reversal, as I am afraid if less exposure was given it would not be sufficient for the general effect. T. E. D.

There is no absolute preventive and remedy. A well plate (the backing applied liberally at home) will give less light, but in any case you must expose a good deal from screened arc in the foreground. We advise you to try chromatic plate (well backed with a black mixture), with which you can give much shorter exposure.

**REFLEX WORK.**—I enclose two postcards, prints from negatives by reflex camera, exposure 1-420 sec.,  $f/6$ , cloudy day. I am obliged if you would criticise them, and say what would be a fair price per dozen to charge for this class of work.—J.

The photograph with the swimmers in the water we consider satisfactory; the sharpest focus should have been in the foreground, not further back, as it is. The diver is and in both cases exposure and general technique very good, save as above mentioned. We advise you to read "Advanced Hand-Camera Work" (Dawbarn and Ward, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100) to price, such negatives, if taken a dozen at a time, should be the least, be worth from 5s. to 10s. each; in very many cases more.

**LENS QUERRY.**—I have bought a set of lenses, supposed to be plate portrait. The loose negative lens is a double concave, this correct, or should it be a concave convex? Could I lengthen the focus by putting a longer focus crossed concave I may require it about 2in. longer than present focus.—G.

We do not clearly understand what you have bought, it is the loose lenses of a portrait combination. In this case should have expected to find a concave-convex meniscus; course, double concave lenses may be used in some combinations. You could lengthen the focus in the water suggest, but you would probably upset the corrections, and into difficulties.

G. P. and Others.—In our next.

FROM "PUNCH."—"Our illustrated newspapers must be careful. To a photograph, entitled 'Signor —' and the Model which appeared the other day, was appended the insulting caption: 'The well-known tenor is distinguished by a X.'"

"ESTONA" COMPETITION.—In the recent competition instituted by the Birmingham Photographic Company, Ltd., for prints of "Estona" self-toning P.O.P., the successful competitors were: first prize (2 guineas), Miss C. Rivers, 21, Greenhill Park, W. N.W.; second prize (1 guinea), W. H. Miles, Combe-St.-N. Chard; third prize (half a guinea), Miss Ida J. Massey, Priory Hale, Cheshire. The work sent in was of a very high standard, and the winners are to be heartily congratulated on their success.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

scheme of certification of cinematograph operators has been a up, and is expected to come into force next October. (P. 574.)

S. D. Chalmers, M.A., is to deliver the Traill-Taylor memorial in October next. His subject is announced as "The Aberra- of Photographic Lenses." (P. 586.)

ssrs. Staley have brought together an interesting exhibition otographs of Holland at their premises in Thavies Inn. (P. 580.)

eral convictions under the Act of Charles II. have been made in the past week against photographers trading on Sundays. (74.)

neras for colour-photography, cinematographs, and stereoscopes mong the patents of the week. (P. 581.)

R. J. Wallace, of the Yerkes Observatory, replies on page o the recent article of Dr. S. E. Sheppard on Mr. Wallace's tomestic investigations.

interesting case connected with the relation of a commercial ller to a firm with whom he has signed an agreement as to reservation of business trusts was decided in the High Court week. (P. 575.)

. Bartlett, before the Philadelphia Photographic Society, has a formula for bright prints on stale platinum paper. (P. 574.)

this week's article on the "Wet Collodion Process" Mr. Foxlee with the manipulation in sensitising and with certain after-sses. (P. 576.)

e have some comments to make on the obligations upon photo- hic apprentices and their masters. (P. 575.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

the Lumière "Autochrome" Plates.—Mr. E. J. Wall gives the ts of measurements of the mosaic filters used in the Lumière ess, and photomicrographs of the grain of the plate. (P. 57.)

J. H. Smith, as the result of experiments in the reproduction umière "Autochromes" on "Uto" paper, recommends a special ting accessory for the purpose of shortening the exposure while nsing with direct sunlight. (P. 62.)

the first portion of an important paper on the Lippmann process ars on page 59.

new dye, "rapid filter blue," has been introduced by Messrs. ster Lucius and Brüning. (P. 62.)

## EX CATHEDRA.

### Hand-Camera Lenses.

Considering the great volume of hand-camera photography, it is a matter for some surprise that the advantages from a pictorial stand-point of a lens of greater focal length than the usual five inches in the quarter-plate are not more generally recognised. Actually the truth of this dictum is confirmed by the skilled hand-camera workers in their own practice, for almost all the finished prints which possess any pleasing perspective are generally enlargements from a portion only of the negative. The use of a lens of longer focus in the first instance is all to the good for more reasons than one. The greater scale of the negative permits of a lesser degree of enlargement, and consequently of less graininess in the enlarged print; and the lesser depth of focus of the larger lens usually means a gain in pictorial quality. We are glad to see that the point of narrower angle of view is not neglected by the opticians. Messrs. Voigtländer, in their latest handsome list, which, by-the-by, contains much general advice on the use of lenses, suggest an angle of 45 degrees when circumstances permit of the focussing being done with the necessary certainty. They give the following table of focal lengths for this angle and those of 55 and 60 degrees:—

Size of Plate.	ANGLE OF PICTURE.		
	45° Focus. Inches.	55° Focus. Inches.	60° Focus. Inches.
4½ × 3½ .....	6½	5½	4½
6½ × 4½ .....	9½	8	7½
7 × 5 .....	10½	8½	7½

It need scarcely be pointed out that a camera of the reflex pattern affords the desirable facility of working at the narrower angle.

\* \* \*

### Dr. Scheffer's Sections.

As considerable interest has been aroused by Dr. Scheffer's exceedingly fine sections of photographic films as to how he obtains them, he has been good enough to send two numbers (Nos. 755 and 756), of "Prometheus," in which he details his examination of the various stones used for grinding microtome and other knives. His articles are illustrated with eighteen photo-micrographs of the surfaces of the stones, and the edges of knives ground thereon, and we can commend these descriptions to the notice of all interested in the matter. Some of the illustrations are very instructive and striking, as they show the effects of the correct and incorrect movement of the knife on the stone, and through the imbedding medium. One good idea of Dr. Scheffer's is the use of brass or aluminium plates damped with water, soapy water, or oil, and sprinkled with a mixture of ten parts of emery powder and three parts of Paris red.

### Sunday Photography.

As has been noticed in our "Notes and News" columns during the last few weeks, the police in some districts have of late been putting that ancient law passed in the reign of Charles II. in force against photographers for Sunday trading. This antiquated and practically obsolete law is rarely invoked except in country districts. In London and other large towns it is seldom proceeded under, as witness the large businesses carried on in some marketing districts during a good portion of the Sabbath. In our issue of last week a case was reported in which a novel defence was set up. A photographer was charged, on three summonses, with trading on Sundays, and the defence was that he practised photography all the week, but his wife took the photographs and the money on Sundays; he only stood at the door on that day inviting people in, and therefore was not following his ordinary calling. The defence was certainly novel, but it did not avail, and the defendant was fined five shillings, the maximum penalty, and five-and-sixpence costs on each summons. It was different in the sixties, at which period, in our recollection, a well-known photographer who had a very lucrative "Sunday" studio in the City of London was, for some time, summoned at the Mansion House every week for carrying on his business on the Sabbath, and was regularly fined five shillings and costs, which he paid, but without altering his procedure. The only fine that can be inflicted is one of five shillings, and it cannot be increased, however many times the person may be convicted. Hence there is little danger of Sunday photography being put a stop to by the enforcement of this ancient law. We may add that under a more recent Act, 34 and 35 V., c. 87, no prosecution for offences under the Act of Car. 2 are to be instituted, except with the consent, in writing, of the chief officer of police of the district or two justices of the peace, or a stipendiary magistrate, having jurisdiction in the place where the offence is committed. Further, no prosecution can be heard before the magistrate by whom or with whose consent it has been instituted. This law was probably passed to prevent vexatious prosecutions by private persons.

### Platinum Prints on Stale Paper.

The use of oxidising bodies as a means of overcoming the veil which naturally results on the development of platinum paper which has lost its pristine virtues through storage in a damp place, or even through long keeping (several years) with every precaution, is, of course, well known, and we have had formulæ recommended in which the chlorates, bichromates, and other per-salts have figured. In a recent paper before the Philadelphia Photographic Society, Dr. John Bartlett avows his preference for the normal or neutral chromate of potassium for this purpose. Half a grain of this substance in one ounce of the normal oxalate developer, diluted with one-third its volume of water, had been sufficient to produce passable prints on platinum paper five years of age. In less severe cases half a grain to every two ounces of diluted developer is described as an ample dose. Though we may query the right of any person to be described as a platinum printer who has paper five years old in his possession, yet the prescription may be of occasional service to those of the still surviving class who would rather spend half-a-day in making shift with old deteriorated material, which at the best will give them but a passable result, than throw all the old stuff away and make a good job with fresh.

### Certificates in Cinematograph Operating.

We are advised by Mr. J. Brooke Wilkinson, secretary of the Cinematograph Manufacturers' Association (whose enviable address is Holborn Restaurant, W.C.), that an examination and certification of exhibitors of cinematograph pictures is to be undertaken by that

body in co-operation with the Northampton Institute. The certificate will be based on a practical examination to be held at the Northampton Institute in October, at which the candidate will work his own machine, one provided for him, and will also answer verbal questions as to the use of illuminants, optical principles of his apparatus, the precautions for safety, and the proper matters of an exhibition. For an advanced certificate subjects are wider in their range, and include a knowledge of the properties of celluloid, electrical manipulation measurements, and other constructional details connected with the cinematograph. We gather from the syllabus that the examination is entirely confined to the exhibition of a cinematograph operator's work; the taking of the negatives is not part of the certification scheme, rightly so, as the public has practically nothing to learn from want of knowledge in this direction on the part of the operator. The examiners in both grades are Messrs. A. C. Bromhead, Robert W. Paul, J. D. Walker, Buckney, A. B. Kent, J. H. Polak. It is to be hoped that qualified operators will have enough *esprit de corps* to take up the certification scheme. Its success rests with them, but if we may anticipate their attitude from that of the photographic assistants, it is not likely that the examiners will be over-worked in October. However, the duties of a cinematograph operator lend themselves better to examination, it is to be hoped that the scheme will receive such support as will safeguard the public from incompetent operators.

### Indicators of Acids and Alkalies.

The means of testing a solution for its acidity or alkalinity is a state as to acidity or alkalinity is of great importance as to which probably many photographers even long experience are not completely informed. A difficulty arises from the various properties of the coloring matters which are used in minute doses to indicate the passage of the solution from faint acidity to faint alkalinity, or its adjustment at the point of exact neutrality. It may be useful, therefore, to give one or two extracts summarising a useful paper on this subject which appears in the current issue of the "Chemist and Druggist" under the signature of Mr. W. S. Clarke. After pointing out that the best indicators are litmus, methyl orange, phenolphthalein, the writer mentions the particular one in which one of these reagents is preferable to the other.

Methyl orange (yellow with alkalies, red with acids) may be employed in the presence of carbon dioxide. It must not be used for organic acids, or in the presence of nitrous acid or its salts.

Phenolphthalein (colourless with acids, pink with alkalies) is the best indicator for use with organic acids. It cannot be used in the presence of ammonia or its salts. If carbonates are estimated by this method, the liberated carbon dioxide must be removed by boiling.

Litmus (blue with alkalies, red with acids) is affected by carbon dioxide. Its use with organic acids is limited. It is not affected by ammonia or its salts.

Thus, in preparing a solution of citrate of potash it will be best to use caustic potash and citric acid with phenolphthalein as an indicator, whilst if ammonia were used in making the citrate of ammonia, the latter reagent would be inadmissible. In making a neutral solution of potassium oxalate for platinum development, oxalic acid and potassium carbonate may be employed, and phenolphthalein or litmus used as an indicator, but in this case, owing to the liberated carbonic acid, the solution must be boiled to expel the gas before the last adjustment of the neutrality point is made.

### Preservatives of Gelatine and Albumen.

A suggestion for the use of pharmaceuticals in photography, but of possible application in photography, is made by Mr. F. H. Allen in the current number of the "Pharmaceutical Journal," where it is pointed out that a solution

albumen or gelatine, the presence in which of preservatives, such as acetic acid, may be undesirable, may be kept in albumen by means of benzine. In its pure state benzine is a highly innocuous body photographically. Mr. Alcock however, uses the cheap commercial variety known as wood naphtha, of sp. gr. .8706 at 60 deg. F., and costing 2s. a gallon. One or two per cent. of this liquid in an albumen or gelatine solution was found to be an excellent preserving agent for solutions of these bodies, and, on account of the neutral character of the benzine, may be found of occasional service in photographic techniques.

#### RIGHTS OF COMMERCIAL TRAVELLERS.

One of those cases which is of interest and importance to every business man was heard in the High Courts last week before Mr. Justice Swinfen Eady, and is reported in the "Times" of Saturday last, the 27th inst. It was an action of a firm of mineral water manufacturers against another firm in the same business. The latter had taken into partnership a former traveller of firm No. 1, and had used his memoranda books and particulars of his former employers' net prices, etc., though the agreement with his previous firm had been at "he shall not nor will not at any time hereafter . . . divulge or make known any of the trusts, secrets, accounts, or dealings of or relating thereto." It was proved that the defendant firm had knowledge of certain of these trusts before the traveller left the plaintiff's employment. The memoranda ordered to be restored to the plaintiff firm included a list of 200 names and addresses of customers, in regard to which there was talk between the defendants and the traveller of "bagging the list." We doubt if the behaviour of the defendant fell below the moral standard in such circumstances, and the damages of £200 in all appear slight if it was assumed that the traveller was to preserve the names of all the plaintiff firm's customers as a secret. The lesson of the case, however, appears to be the importance of a clear understanding as to a time limit or some other restriction which a traveller may assent as to the use of information acquired while in the employment of his firm.

#### PHOTOGRAPHIC IMPROVERS, MASTERS, AND THEIR OBLIGATIONS.

We are continually receiving letters from those who have been apprenticed to the photographic profession complaining that, after serving their term, they have been taught little beyond printing and toning, and, perhaps, retouching; also that they know little or nothing of studio work, and, consequently, are quite unable to obtain employment as operators, although they should be fully competent to do so. Some photographers, far too many we fear, take apprentices more with the object of getting a premium; or with the view of getting some one, after a little tuition, to do the work they require of them, for a term of years—usually three or five—for a quite nominal wage, sometimes for practically no wage at all, without giving any really valuable tuition in return which would make the apprentice a thorough craftsman. Some who take apprentices with these objects in view do not seem to realise the responsibilities they incur, or the trouble they may get themselves into in the event of their not being fully carried out. A photographer who takes an apprentice is bound to fully teach him all branches of the business as carried on by him; not merely to teach him, we will say, printing and toning, and, perhaps, retouching, or other work he, the master, wants done. He must also, if it is a portrait business, fully instruct him in lighting and posing, managing

sitters, and studio work generally. Unless the apprentice is fully taught his business throughout the master becomes liable not only to have to return the premium, if one was paid with him, but also lays himself open to an action for damages for the apprentice's loss of time while serving his term.

As misconceptions evidently exist, both with masters and apprentices, as to the rights of each, we shall here give some points with regard to those of both. In the first place, when apprentices are bound, there must be legal indentures, signed by both parties, fully setting forth what the apprentice is to be taught. These should, preferably, be drawn out by a solicitor, and must be stamped with a two-and-sixpenny stamp. Unless the indenture is duly stamped it is not binding on either party, and the apprentice becomes merely a weekly servant, who can leave at any time on giving a week's notice. On the other hand, the master can discharge him on similar terms.

An apprentice cannot be compelled to serve after he attains the age of twenty-one. Supposing, for example, a youth is bound, at the age of seventeen, for five years—a very general term in the photographic profession, though it is often three years, particularly in the case of females—he, or she, is not bound to serve after the age of twenty-one unless he chooses to do so, and the master cannot compel him. Now, a female who is apprenticed, we will say, to learn retouching and reception-room duties should, if she were properly instructed, be fully competent to take an engagement as a retoucher and receptionist, but in very many cases she is not. Hence, when a female has served her term, she frequently has to take an engagement as an improver for a time at quite a nominal salary. The same thing often occurs with male apprentices. After serving three or five years' apprenticeship they are also compelled to accept an engagement as an improver at quite a trivial salary. With the present dry plates and ready sensitised papers, there is nothing in ordinary every-day photography in which any person with ordinary intelligence should not be made thoroughly competent in all respects, during an apprenticeship of five or even three years if properly taught as he ought to be by the master.

An apprentice, we ought to add, is not bound to serve after he has arrived at the age of twenty-one. But it will be as well to say that if any one, after that age, apprentices himself he is bound to serve the full time agreed upon whatever it may be; he, being of full age, is capable of contracting for himself. That is not the case with a minor, as with him it is the parent or guardian who is the contracting party.

In connection with the term "improvers," it is noteworthy that some who advertise for these services stipulate that they must be competent in all branches. We recall to mind an advertisement of a provincial photographer which, some little while back, asked for an improver who must have had at least seven years' practical experience in a first-class London house. One would not, unnaturally, have surmised that any one who had seven years' experience in a high-class London establishment could scarcely be classed as an improver. Some of those who, at times, advertise for assistants as improvers expect them to be really efficient workers, and to be able to do all they require of them, but at a lower salary than they would have to pay if they advertised for an assistant in the ordinary way.

A few of the legal aspects as regards masters and apprentices will now be explained. The law with regard to them is very stringent indeed, and local magistrates and justices of the peace have full power to apply it in all cases; hence there is no necessity for costly legal proceedings. In the case of a dispute between an apprentice and his master the local magistrate, or justices of the peace, can settle the

matter at once on the application of either party. If, for example, the parents or guardians of a youth find that he is not being properly taught his trade according to the terms of the indenture the master can be summoned before the magistrate, who, after hearing the case, and finding it proved, has the power to order the premium paid, or any portion of it, to be refunded, and the indentures cancelled. Not long ago a case was reported in the daily papers where a youth had been apprenticed to the ironmongery business, and the master was proceeded against for not properly teaching him the business. The defence was that as the apprentice had the run of the shop he had full opportunity of learning the business. This, however, was held to be not thoroughly teaching it, and the master had to refund a good portion of the premium he had received.

The indentures may be cancelled by a magistrate on proof of wilful misconduct by either master or apprentice, or of wilful disobedience or misbehaviour of the apprentice. If the master dies the indentures are dissolved—the interest being a mere personal trust—but if the apprentice

is bound to two masters, say partners, then he becomes the apprentice of the survivor. The bankruptcy of the master also dissolves the apprenticeship, and the Court may order the premium paid, or any portion of it, to be refunded out of the estate. Should a master give an apprentice licence to leave him he cannot afterwards recall it. If an apprentice absents himself from his master's service the magistrate is empowered to order him to serve out absent time, or make satisfaction for it, and in default may be committed to prison. If, however, an apprentice has served a full seven years he cannot be compelled to serve longer.

The above are some of the chief legal points that are of interest to those who take apprentices, and to those who are apprenticed. In binding an apprentice to a photographer it should clearly be set out in the indentures what he, she, is to be taught, and it is then the duty of the partner or guardian to see that it is thoroughly done, and, if necessary, that proceedings are taken to enforce the conditions of the indentures.

## THE WET COLLODION PROCESS IN PRACTICE.

[The following article deals with the manipulation of the wet collodion plate when sensitising and developing. In previous articles Mr. Foxlee has dealt with the earlier stages of the process, including the cleaning of the plates and the preparation of collodion and bath. The succeeding chapter will give instruction in the use of the process for glass positives and negatives.—Eds. B.J.]

SOME of my readers may possibly consider that in former articles, and perhaps this, I am somewhat prolix, but, as I said at the commencement of them, success or failure in the collodion process depends upon quite trivial things, and that is the reason for the apparent prolixity. With this remark we will resume our subject, reverting to the last article.

### Manipulation in Sensitising.

The collodion having set to the necessary state, the dipper is withdrawn from the bath and the plate placed upon it, and gently lowered in the solution. This must be done without hesitation, as the slightest stop or check in its immersion will cause a line which is certain to show in the negative. When the plate is completely immersed it is, on the dipper, slightly agitated by moving it laterally in the solution for a few seconds. After being in the bath for a minute or two the plate is quickly withdrawn and replaced a few times; this will facilitate the removal of the solvents of the collodion. The plate is then allowed to rest for a few minutes, according to the temperature. If when the plate is again withdrawn it shows no signs of streakiness it is ready for exposure. If it shows streaks it should be replaced until the solution will drain off perfectly even, and with no signs of streakiness. The plate should then be drained for a minute or two on a pad of blotting-paper, and the back wiped with a piece of blotting-paper. This prevents any superfluous solution draining off into the dark slide. The slide should be carefully dusted before the plate is put into it and the best duster to use for the purpose is a slightly damp skin of chamois leather, as that is quite free from fluff, and takes up the dust readily.

We have here been assuming that the dipping-bath is the one employed. But if the wave bath, described in a previous article, be used—and that is far the preferable for large-size plates—the plate is placed on the ledge or pegs provided for the purpose (the bath being in the upright position). The cover is then closed, and the bath lowered to the horizontal position without any stoppage, when the solution will flow over the plate in an even wave. If any check were made in lowering the bath a mark would be made as in the case of a stoppage with the dipping-bath. If the bath be then slightly tilted

up and down a few times it will aid in the removal of the excess of collodion. When the plate is completely sensitised the bath is again brought to the upright position, when it may be left draining without further trouble. As the atmosphere within the bath is saturated with moisture, the plate may be drained for even half an hour or more without fear of its becoming dry. Indeed, this long draining is a great preventive of what are known as "oyster-shell" markings.

### Sensitising in a Flat Dish.

If an ordinary flat dish or tray is used for the sensitising some little dexterity, or knack, is necessary to avoid lines. The method is usually as follows:—The vessel is tilted so that the upper end is free from the solution. One end of the plate is then rested on the empty space, then it and the tray are lowered simultaneously to the horizontal position, so that the solution flows over the film in an even wave. This vessel is then gently rocked to and fro.

Before the plate is put into the slide, pieces of blotting-paper should be placed on the bottom corners for it to rest upon, and also to absorb any of the bath solution that may drain from the plate. It may be well to state that the sooner the plate is developed after it is sensitised and exposed the better, particularly in hot weather, as then the film quickly dries. If there is a suspicion that it has somewhat dried, it is a good plan to re-immers it in the bath for a few seconds before developing.

With regard to the exposure, nothing that would be of a real service can be said; but the worker who is familiar with the working of gelatine plates will at once recognise whether the negative has been rightly timed or not. The characteristics of under-exposed or over-exposed collodion negatives are precisely the same as those of dry plates.

### Applying the Developer.

When the exposed plate is taken from the slide it is rested upon a pad of blotting-paper for a few seconds to absorb any superfluous solution there may be on the bottom, as that may possibly be charged with impurities. Sufficient of the developer to well cover the plate, and not more, is then put in a glass cup or beaker; if the plate is large an ordinary glass

ble is a convenient vessel for the purpose. The plate is taken by the corner—the one by which it was held while coated with the collodion—and the developer poured gently along one edge, avoiding air-bubbles, which would produce streakings, and caused to flow in one unbroken wave over the face. If any stoppage in the flow be made a mark of uneven development will be produced. The solution is then made to flow to and fro and backward and forward, when the image will fully appear. Care should be taken to spill as little as possible of the developer, as it would carry away with it some of the free silver, and thus lessen the density in the first development. It should be kept in mind that in the collodion process development is physical; the image is formed by the precipitation of silver. It might here be mentioned that if the plate, after exposure, were washed free from silver, the developer would fail to bring out the image unless some silver were added when it was applied. Therefore, it will be seen that the free silver there is on, and in, the film during the development; the less will be the density in the image obtained in the first development. Therefore, the desirability of using only a minimum quantity of the developer, and spilling as little of it as possible, will be easily recognised.

#### Remedying Errors in Exposure.

From the way in which the image appears it is easily judged whether the exposure has been correctly timed or not. If when the high-lights first appear they are quickly followed by half-tones, and then by detail in the shadows when viewed by transmitted light—the developer being momentarily drained back to the cup to permit of the examination—the exposure will be about right. The developer is then returned to the plate and flowed over as before, when the density will go on increasing. When no more can be got with the iron the plate is well washed, and is ready for intensifying. If the image does not prove tardy in making its appearance, and the shadows are wanting in detail, under-exposure is indicated, and the developer with iron should be forced by keeping the solution longer on the plate. When the developer becomes muddy from the precipitation of silver it should be thrown off and a fresh lot, after the addition of a few drops of silver solution has been made, used. This may be poured, locally, on and off the darker portions of the picture. In this way detail in the shadows may be gently but coaxingly brought out, provided the under-exposure has not been too pronounced. Of course, with this continued development the lights have been gaining density the while, and it is quite possible that the negative will require no after-intensification. Should the image come out all over at once it is a clear sign of over-exposure, and the action of the developer should be stopped at an early stage by washing the plate, and after intensification relied on for the ultimate density. In a case of much over-exposure the negative with advantage may be used before it is intensified; that will give clearer shadows, and the intensifier does, to an extent, bring out more detail when it is used before fixation.

When the developer is applied to the plate it does not freely over it, more alcohol must be added. When the developer-bath is old and well charged with the ether and alcohol the collodion the film is somewhat repellent of the developer, but that is quite remedied by the addition to it of a little spirit.

After the image has been fully brought out by the iron developer, the negative is thoroughly washed under the tap. There will probably be some reduced silver on the back of the plate. This should be cleared off with the fingers if it is of small size. If large plates are in use, a piece of sponge should be kept handy for the purpose. When well washed, the negative can be examined at leisure. If it is seen to have the correct exposure it may be intensified, either before or after fixation; but if it is at all under-exposed, it is best to intensify before fixation, because, as already mentioned, some

little detail is brought out by the pyro intensifier. If, however, the negative proves to be much under-exposed, it will be well to intensify it with the iron developer, with a drop or two of the silver solution added, as then, during the operation, a little more detail may possibly be brought out. Should, however, the negative turn out to be over-exposed, it should certainly be fixed before it is intensified. Intensification before fixation tends to softness in the negatives, and after fixation to vigour or hardness, if carried too far. If the negative is fixed before it is intensified, it should be very thoroughly washed, otherwise staining may occur.

#### Intensification.

Whether the negative is fixed or unfixed, the procedure is the same. A little—just sufficient to flood the plate—of the intensifier—the formula for which has already been given—is put into a glass, which, by the way, should be specially kept for the purpose, as it is not advisable to use the one employed for the iron. Two or three drops, according to the quantity taken, of the silver solution are then added, and the whole flowed over the plate in the same way as was the iron developer, and then poured on and off, watching the effect, of course, by transmitted light. By pouring the developer direct on and off, certain portions may be somewhat locally intensified. The intensifier, it is pretty generally known, acts by precipitating more metallic silver on the parts acted upon by light, thus increasing their density. After a few minutes the intensifying solution will become more or less muddy by the reduction of silver in it, and if by the time this occurs the negative is not dense enough—and this may happen in hot weather—it is thrown off, the negative rinsed under the tap, the glass washed out, and fresh intensifier mixed and applied as before. When sufficient density is obtained, the negative is well washed back and front, and is ready for fixing. The iodised collodion film being so much more transparent than a bromide gelatine one, the increasing density of the former is more easily judged. If, after a negative has been intensified and fixed, it is thought that the image is still not quite dense enough, the intensification can be repeated.

As already mentioned, we have the choice of two fixing agents—cyanide of potassium and hyposulphite of soda—and they may each be used over and over again; also, they may be employed by pouring them on and off the plates, or as baths. When the former is used as a bath, it is advisable to employ a dipping-bath rather than a flat tray, as then, by reason of the smaller surface of liquid exposed, less of the objectionable fumes of the cyanide are given off. A collodion negative fixes far more rapidly than does a gelatine one, and two or three minutes are usually sufficient, even with hypo when the solution has been but little used.

#### A Powerful Intensifier.

For all ordinary purposes, ample density will be obtained with the pyro-silver intensifier, but for some purposes, such as the reproduction of line subjects, maps, and the like, other methods are sometimes necessary. In these cases the negatives must always be fixed before they are intensified. The following is a method I have seen employed at the Ordnance Survey Office, Southampton, in the reproduction of maps. The negative is first immersed for a short time in the following solution:

Sulphate of copper .....	4,000 grains
Bromide of potassium .....	2,400 „
Water .....	80 ounces

After washing, the negatives are flowed over with a tolerably strong solution of nitrate of silver—100 grains to the ounce. This gives great density with exceeding clearness to the other portions.

The following is also an excellent method:—The image is first bleached in a saturated solution of bichloride of mercury

and well washed. It is then blackened in the following solution:—

Nitrate of silver .....	200 grains
Water .....	1 pint
Cyanide of potassium .....	20 grains
Water .....	2 ounces

The cyanide solution is added gradually to that of the silver until the precipitated cyanide of silver is nearly, but not quite, dissolved. Should too much be used so that the whole is dissolved, a little more silver must be added, as it is necessary that there should be a little undissolved cyanide of silver left in the solution.

In addition to these there are other methods; indeed, collodion negatives may be intensified by almost any of those used in intensifying gelatine ones. It may be mentioned here that the more silver there is in the negatives to begin with the greater is the ease with which increased density is obtained when required, and fully-exposed negatives intensify much more readily than do under-exposed ones. Therefore, when great density is required the negatives should be fully exposed in the first instance.

After the negative is fixed it is thoroughly washed under the tap; this only requires a few minutes, as the film is so very thin as compared with a gelatine one. But negatives fixed with hypo should receive a little more than is necessary with cyanide. The negative, after drying, is ready for varnishing, and the drying may be done before the fire if time is an object.

#### Varnishing.

The best varnish for collodion negatives is a hard spirit varnish, of which shellac is the base. Formulæ for several are given in the *BRITISH JOURNAL "Almanac,"* but as good negative varnishes are sold by the dealers at such very moderate prices it is a question whether it is not better to purchase ready-made than to make them for oneself. The negative should be warmed before the fire, or over a gas-stove, but only sufficiently to take the chill off the glass and to prevent the varnish from chilling. The varnish is then flowed over as when coating the plate with collodion. If the plate is made too hot the varnish will not flow freely, and will be likely to dry in ridges. After the plate has been coated, and the excess of varnish drained back into the bottle, it is held before the fire and made as hot as the hand can well bear. When cold the negative is ready to be printed from, though it is better to let it rest for an hour or so before the printing. The varnishing with spirit varnish greatly increases the

transparency of the shadows, and if the chemicals were working order the deepest points of shadow will be represented by absolutely bare glass, such as is never seen in gelatine negatives.

#### Transparencies by the Wet Collodion Process

The collodion process is still largely employed commonly for lantern transparencies. It goes without saying that it must be made in the camera, as contact printing would be of the question. The manipulations in producing them differ materially from those in the production of negative points to be kept in view are that the highest lights are represented by absolutely bare glass, as the shadows have to retain transparency, and be not dense and heavy. To secure conditions in the full the silver bath may be made slightly acid than is desirable for negatives. The collodion, if possible, should be iodised three months or more before it is used, newly iodised has to be employed it should have a like strength of iodine in alcohol added to it so as to give it a deep tint; exposure should be a full one; as any approach to under-exposure would lead to hard and inky-looking slides. Development with iron should be arrested as soon as full is obtained in the deep shadows, and the plate washed, and then again well washed under the tap. It is then intensified with the same intensifier as for negatives, which yield black tones. If warmer ones, however, are required it is better to omit the citric acid, as that tends to coldness, and to use it by a larger proportion of acetic acid, which gives a warmer tone. A good formula is:—

Pyrogallie acid .....	25 grains.
Glacial acetic acid .....	1 ounce.
Water .....	10 ounces.

In intensifying lantern slides it is a good plan to first intensify over the plate two or three times before the intensifier is added to it, as then it permeates the film and seems to give a warmer tone than when the silver is added in the first instance. If the exposure has been right sufficient density will be obtained, but as soon as the intensifier shows any signs of excess it should be thrown off, the plate rinsed, and fresh aqua as the solution with the acetic acid alone does not keep so long as when it contains the citric acid, and if it were used in a muddy condition the lights might suffer. Should the transparency when dry show a slight opalescence in the shadow will entirely disappear when it is varnished with a spirit varnish.

E. W. Fox.

## THE DAYLIGHT SENSITOMETRY OF PHOTOGRAPHIC PLATES.

(Reply to "Comments" of Dr. S. E. Sheppard. See "B.J.," June 7, p. 425.)

In a former paper the writer advanced a method for "The Daylight Sensitometry of Photographic Plates, and a Suggested Standard Dispersion Piece," which was reprinted in the "B.J." and courteously commented upon in an article by Dr. S. E. Sheppard (June 7).

While it will be obvious that we cannot enter into a continued discussion at such long range, it appears that on purely scientific grounds a reply is demanded to certain points raised therein, and which may otherwise be delayed in publication by pressure of work from my regular duties.

Primarily these papers are addressed to those who are making use of photography as a means of recording scientific data, hence there are many points which are not expatiated upon at length, because the assumption of the reader's knowledge is definite and assured. For example, it would not be advisable to explain in detail what is meant by prismatic "irrationality,"

or to attempt an exposition of the principles involved in the formation of the diffraction spectrum, because the majority of men capable of the interpretation of investigative work in the photographic plate already have sufficient general chemical, physical, optical, etc., knowledge to render them immune from such an infliction.

Nevertheless, although it is to those individuals primarily that such papers are addressed, yet it must not be lost sight of that the main object of all publication is "the diffusion of knowledge." The method adopted for such "diffusion," unfortunately, does, in the mind of the layman, sometimes rather as confusion, and this is still further accentuated by many disagreements among the authorities themselves. In many cases, however, these same disagreements, when properly analysed, resolve themselves into detail which has no practical bearing upon the everyday sense) bearing upon the

ts at issue. Take, for example, the publication of the spectrum of some dye stuff illustrating its value as a filter in photographic work. It would be altogether the point were some other worker to comment upon the fact that the distilled water in which it was dissolved possessed itself a definite absorption. It would be an incontrovertible fact, but a very unnecessary one, because, as ordinarily used, it would be an impossibility for the absorption spectrum of the water to influence the work in view.

eg, therefore, that this present article may be considered supplementary to my paper on Sensitometry No. 1, and that it may serve to close up some of the gaps existing in the greater number of readers.

Referring first to the Hufner spectrophotometer, I should be deeply regretful did the reading of my paper convey the impression that I "under-rated" the instrument. Such was not my intention. The Hufner instrument was constructed for me by Gaertner, of Chicago, and the optical design by Petitdidier, of the same city, and I am sure that the names are sufficient guarantee of its excellence, for it is safe to say that there is scarcely a scientist of note in the United States (and but few in Europe) who are not indebted to both of those workers for investigative apparatus of the highest order of merit. Special care was taken that the arries on the rhomb should be sharp "knife edges" and of 20 mm. length, so that in the event of accidental damage to them, they would still be present sufficient surface to allow of its being displaced laterally along the slit-plate, and thus admit the use of a new and more perfect edge.

When adjusted to the instrument, separate slow-motion screws conveyed movement to the rhomb or the Nicol independently, and (the spectrometer having been critically adjusted in the usual manner) all possible conditions were experimented with, not only by rhomb movements, but also by alteration of the angle of the light incident upon its faces; at no position did it found possible, however, to eliminate the dividing line separating the spectra. To throw the telescope out of focus was even considered, because in the various lines of work for which the instrument was intended the comparison of spectral lines occupied a large place, and inasmuch as such lines are separated by the slit, the elimination of the rhomb dividing line would mean the elimination of the absorption (or emission) line. Here is, however, a much more serious objection (from the point of view of the scientist) to this "out of focus" method of operation, and one which must, of course, be well known, namely, the fact that such a procedure means the mixing of two beams (the polarised and the absorbed light) to an amount dependent upon the amount of displacement of the rhomb from the point of critical focus.

It is the endeavour of all experienced photometrists to obtain two lights under comparison as close together as is possible, as it is not conducive to good measurement when the observer has to "jump" from one portion of the field to another, in the case of two lights immediately adjoining one another. "Match" is made directly at the point of contact, independent of whether the illumination covers an area of 1 mm. or 20 mm., hence, in the "out of focus" method with the rhomb, use will be made of just the region of greatest contrast, and for purely scientific work it will be obvious that a method would not be advisable if a better could be obtained. That the Brace prism presents such a betterment to the photometric worker who has used both instruments can for the moment deny, for the two lights accurately adjoin—there is no dividing line—and there is one critical point of balance which is so definitely perceptible to the eye, that after much experimental work by several observers of known reputation, the recording of single settings ("above" and "below") now gives the mental mean of three as was formerly used. The "automatic subtraction" of the fog-value by the Hufner

instrument does not appeal to the writer as possessing any advantage over the arithmetical subtraction in so far as accuracy is concerned, although it will undoubtedly save a modicum of time. In high-power work the use of a short-focus eyepiece will obviously enlarge the doubtful zone and render it still more dangerous.

It may be well to state, here and now, that the real practical differences in the results between the two instruments are, generally speaking, non-existent. For photographic measurements the Hufner spectrophotometer or the modified Brace instrument give results which, when use is made of ordinary plates, are really far in advance of that required, and for specially coated plates are equally capable of an extremely high degree of precision. No one of experience would for a moment question the accuracy of measurements made by the Hufner any more than they would by the Brace, the only difference being that the latter instrument is more sensitive, and is suited for a greater variety of work.

Regarding the experiments by Twyman upon the error in polarisation spectrophotometers, it is perhaps sufficient to refer those interested to the detailed plan of the modified Brace instrument. Comparison between curves of the same plates measured in it, and also in the Hartmann microphotometer (two instruments totally different in principle) show an extraordinary exactitude. Again, the measurement of a plate in all four quadrants of the instrument presents a series of curves which lie almost directly one upon another, and following precisely the same mean path. Altogether, a very large amount of experimental work was performed in the arrangement and adjustment, extending over a period of eighteen months, which need hardly, even here, be enumerated in detail; the assumption of sufficient knowledge in the builder of such an instrument might naturally follow, when associated with what one considers a somewhat extended photometric experience with a large number of instruments.

The formation of the image of an intensely blue sky or white cloud upon the slit-plate of the spectrograph is, in the opinion of the writer, certainly an extremely wide range of contrast, and one which it must be admitted embraces very abnormal conditions. It is, however, a fact very easily verified, that the secondary maximum of the Cramer Instantaneous Isochromatic plate increases with a higher ratio to exposure than does the blue-violet, after the inertia of the plate has been overcome, and a slight preliminary action established. I would also point out that in the plates selected for measurement and illustrated the greatest density in the violet at  $\lambda$  4,120—1.2 (H and D), a density of less than half a normally exposed plate, and by no means anywhere near the region of over-exposure. Under these circumstances, therefore, I can see no good reason why it should not be perfectly proper and correct to have made use of another negative, had such been available, more nearly approximating equality in the violet. Incidentally, the fact must not be lost sight of that the introduction of the ground-glass—which is the method proposed—does, on the same sky effect, reduce the difference to a very favourable mean<sup>1</sup>. It may also be remarked that these results are verified by about thirty separate plates on various dates.

He would be bold indeed who should claim absolute exactitude for any suggested method of sensitometry, but the writer does claim that daylight, even with this known variation in spectral intensity, is—at least—as accurate in its results as is any form of artificial light in which the ultra-violet—the region possessed of almost the greatest photographic activity—is sadly deficient, and for which, together with the false intensity distribution, approximate compensation filters have to be prepared by individual workers.

<sup>1</sup> It is unfortunate that in the reprint by the "B.J." these curves (Fig. 7, p. 408) are not individually specified. The central curve is "ground glass," while the upper and lower are "white cloud" and "blue sky" respectively.

Surprise is expressed that the H and D inertia is not accepted in the method proposed by the writer, and in reply to this I would say that by no means have I been satisfied with this value. On the contrary, my experiments point to considerable variability when working with the same plates, even when the constants—developer, time, and temperature—were kept rigorously exact. The writer is well aware of the findings of Messrs. Mees and Sheppard, but it is to be regretted that at present I cannot make results conform to those obtained by these capable and painstaking workers: continued experiments may, of course, modify or even change my present views, but, at present, I regard the inertia, as ordinarily obtained, as being of doubtful value, when we take into consideration that the straight portion of the characteristic curve is, in reality, not straight at all, but possesses a decided point of inflection.

For several years the writer experimented with the use of broad-banded filters, which divided the spectrum first into two portions (Eder), and later, with approximate equality in luminosity, into four, but the method was in my hands found lacking in reliability. Qualitatively they were very good, but, although carefully compounded and their transmission definitely known, readings behind them always must lack the quantitative value which can be obtained from a series of daylight spectra by anyone accustomed to their reading. This appears to the writer so sufficiently obvious as to require neither explanation or exposition.

The plotting of spectral results in terms of density and wavelength, which, it might incidentally be mentioned, is the method adopted by Mees and Sheppard themselves, constitutes, in the writer's opinion, the only valid method of practical use. To make use of either the bolometer or the radio-micrometer and plot "work equivalent" appeals to my mind as being about the most "round-about" method that could possibly be suggested when we consider just what is wanted. The experiments of Abney relating to the alteration of the gradation curve by light of different wave-lengths must not be confounded with the spectral curve obtained in the manner which I have described, and which is checked and supported not only by the exposures preceding and following, but also by the method of development. The action of the spectrum of diffused daylight will always exercise the same mean effect upon the same plate, at any particular wave-length, when these precautionary measures are fulfilled, and, I would add, is a point which has been confirmed by many hundreds of plates. I am sure there is no necessity of repeating or enlarging upon the substance of my fifth paragraph under the sub-title "Colour-sensitiveness"<sup>2</sup> further than to again regret the impossibility of agreement in regard to the quantitative value of broad-banded filter tests by artificial light, against daylight spectrum exposures. Attention has previously been directed to this point in connection with chromatic sensitiveness ratios by another writer<sup>3</sup>, but, unfortunately, the matter was not carried sufficiently far forward.

In conclusion, I would state that it would cause me much chagrin should Messrs. Mees or Sheppard consider that I have failed in appreciation of their most able and excellent work. Experience forbids acceptance of all points contained therein, however, although every scientific investigator knows that results must generally be accepted provisionally. Often that which is at the present so fair and plausible, so encompassed about and supported by apparent facts and well-known "laws," becomes, in the light of continued experiment, untenable; furthermore, it is always well to bear in mind the idea so ably expressed by Mellor,<sup>4</sup> as follows:—

"It must be pointed out that an hypothesis *after* passing through the mathematical mill is neither more nor less entitled

to confidence *them before*. The appearance of accuracy by the mathematical symbols is illusory. . . . The prevailing notion that the agreement between the "calculated" and "observed" results is an infallible crucial test hypothesis. The agreement only shows that the hypothesis *be true*."

Instructor in Photophysics,

Yerkes Observatory, June 22, 1907.

## Exhibitions.

### PHOTOGRAPHS OF HOLLAND AT MESSRS. A. STALEY AND CO.'S.

THERE is now on view at the house of Messrs. A. E. Staley & Co., 19, Thavies Inn, Holborn Circus, London, E.C., a collection more than a hundred photographs by Mr. Stanley E. F. which for more than one reason are quite deserving of a visit. The photographs are all of scenes, people, and incidents in Holland reproduced with great fidelity the many picturesque subjects met with in Dutch town and country. The tourist, and especially the busy Londoner, who can spare but a few days from business holiday, will also be interested to know that the whole series of pictures was made within a period of fifteen days, and lastly is the additional fact of interest in connection with the exhibition that the prints are obtained in almost every instance from negatives made with Messrs. Staley's "Euryplan" lens. A few instances of the "Planastigmat" of the same firm was used, but the great majority of the prints owe their existence to the more recent introduction. The visitor to the exhibition obtains a very good idea of the capabilities of these direct lens prints, but by comparison of the latter with the former prints which in a number of cases are included. One or two particularly, in which the rigging of a ship occurs in the corner of the frame, show the great and sharp covering power of the "Euryplan." In no case, we were told, was a smaller aperture than  $f/11$  employed, and most of the outdoor scenes were done with an aperture,  $f/6$ , of the "Euryplan." Many of the interior subjects are of critical definition, and we believe the visitor to the exhibition will agree with us in the admission that they obtain it to a degree from the "Euryplan." On the pictorial side a good deal must be said for several of Mr. Fincham's selections, but his aim is evidently technical, and he, we believe, would be the last to accuse us of misunderstanding it were we to embark on a judgment of his work in comparison with what is commonly understood as "individualistic" or "pictorial" work.

INSTRUCTION IN LIGHTING.—While so much stress is laid rightly—on the importance of a proper study on the part of the photographer of the management of the studio lighting it may be welcome news to many to hear of anyone who is ready to adopt a system which has the testimonial of his own good work, who is also prepared to explain its adaptation to particular subjects. We are therefore glad to draw attention to the course of instruction offered by Mr. Robert A. Higgs, of Glendine, St. Mark's, Chelsea, under the title "The Royal Road to Lighting." From what we have seen of Mr. Higgs' work and his correspondence with those who have attended his lessons, we can say that he is able to explain his system of lighting and that the adoption of his methods have been an obvious benefit to those giving their attention to the matter. Mr. Higgs is evidently both competent and painstaking, and there is good reason for recommending him as a counsellor and guide to those anxious to improve their studio practice.

PHILIP HARRIS, a colour etcher, living at Watford, recently committed suicide by taking cyanide of potassium. He had been in ill-health for a long time, and the jury returned a verdict of "Suicide" whilst temporarily insane."

THE employees of The British Art Co., of Essex Road, N., spent their annual outing to Margate on Saturday, July 27. The outing was served at the Imperial Hotel, over which Mr. B. Seldt presided. A most enjoyable day was spent.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been made between July 15 and 20:—

**CAMERA.**—No. 16,326. Improved pocket camera. F. Matuschek, 116, High Holborn, London.

**DEVELOPING.**—No. 16,411. Improvements in and relating to means for developing photographic plates, films, and the like. Percy Albert Craven, 11, Maiden Lane, London.

**PAPERS.**—No. 16,509. Improvements relating to sensitised papers for photographic purposes. Ernest Howard Farmer, 8, Quality Court, Chancery Lane, London.

**PRINTS.**—No. 16,510. Improvements in photographic prints and printing appliances. Ernest Howard Farmer, 8, Quality Court, Chancery Lane, London.

**FOCUSsing.**—No. 16,569. Improved means for focussing photographic cameras. Herbert Holmes, William Albert Edwards, and Houghtons Ltd., 88, High Holborn, London.

**FOCUSsing SCREENS.**—No. 16,620. Improvements in or additions to the focussing screens of photographic cameras. Percy George Potter, 35, Temple Row, Birmingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**STEREOSCOPES.**—No. 29,419, 1906. For each stereoscopic slide two glass plates are used, of which the front plate serves as the plate for the reception of the photograph and the rear plate has a surface for receiving the painting in the desired colours. The colour plate has all the atmospheric parts of the picture which are particularly difficult to reproduce by painting, uncoloured, and instead of this a translucent green is placed in front of the source of light upon which the colours required are placed. In this manner it becomes possible to make every separate part of the picture appear in the natural tint. As between the eye of the beholder and the translucent screen the colour plate has been interposed so that the sharp lines of the different tints which appear on the screen are no longer visible (in contradistinction to the process in which the requisite colours are all applied direct to the colour plate) and as in consequence of the diffusion of the light rays and also by reason of the refracting influence of the colour plate, the sharp outlines of the tints on the translucent screen are toned down and mixed, there is produced an extremely harmonious effect, which comes extraordinarily close to nature. August Fuhrmann, 27, Lichterfelder Strasse, Berlin.

**INEMATOPHGRAPHS.**—No. 16,771, 1906. The invention consists essentially in locating on one of the sprocket drum shafts, by which the film is taken through the machine, an improved differential gear apparatus, a portion of which may be adjusted by mechanical means in such a way that the speed of the sprocket drum, and consequently the speed of the film, shall be readily accelerated or retarded. The first claim is:—

1. In a cinematograph apparatus a different gear connected with one of the sprocket drum shafts, consisting of a worm wheel adjustably-operated as required by a worm and shaft and loosely mounted on the sprocket drum shaft, a bevel wheel forming part of or attached to said worm-wheel, a second bevel wheel secured to or forming part of the sprocket wheel for moving the film mounted loosely on the sprocket wheel shaft, a boss secured to or forming part of the shaft, a shaft carried by said boss and a bevel wheel secured to said shaft, gearing with the two bevels previously referred to. Henry William Joy, 80, York Avenue, Manley Park, Manchester.

**PRINTING MACHINE.**—No. 16,507, 1906. The invention consists of a frame for the rapid printing of bromides, etc., from midget and other photographic negatives. Fig. 1 shows the repeating frame. D and E are square rods which run in grooves, they can

be drawn out from the end and are reversible. These rods do not run in the grooves at right angles to the surface of the frame, but are set diagonally. The top corner projects above the surface of the frame, and each of these corners are cut at various distances. The distance of these cuts or notches is exactly the same as the width of the negative to be printed. The negative is placed in position between A and B, the edges of which are rebated to carry it. A is a moving part and can be adjusted to hold negatives of various sizes. The lower part of this strip

travels under C, the object of which is to prevent light from coming through the frame. B is fixed, and forms the abutment of one edge of the negative.

In using this repeating frame the negative is placed in position between A and B, and supposing the width of the negative is  $3\frac{1}{4}$  ins. then one of the rods must be used that has the notches the same width ( $3\frac{1}{4}$  ins. between each notch). One edge of the negative is at B, and the ends of the strip of paper are placed on the negative and brought in close contact by means of a pressure board, which works on double-jointed hinges. The exposure is then made, and the paper moved along to the first notch and again exposed, and this is repeated until the whole sheet is used. Alfred Gabriel Tooth, 67, Miall Road, Sydenham, S.E., John William Riley, photographer, 40, Stockwell Road, Brixton, S.W.

**NON-FILTER ORTHO PLATES.**—No. 25,906, 1906. The invention consists in the use of non-colour-sensitising dyes for the purpose of making the sensitive plate act as a light filter for itself, without affecting its colour-sensitiveness. Dyes mentioned are "yellow picrate," naphthol orange, canary yellow, alizarin yellow, tartrazine, aurantia. Otto Pfenninger, 105, Hythe Road, Brighton.

**ONE-EXPOSURE CAMERAS FOR COLOUR-PHOTOGRAPHY.**—No. 25,907, 1906. The following extracts from the specification describe the invention:—

"Fig. 1, which is really Bennetto's patent, we find that the light rays coming from the optical centre or lens 'O' are partly reflected from the transparent red reflector to the top, marked 'R R' and also marked by lines with dots.

"The transparent reflector 'T' is really a glass plate, which carries the red screening material at the back surface.

"All the inventors mentioned in these specifications supposed

Fig. 1.

Fig. 2.

that the light rays coming from 'O' would go through the red screen 'T' straight to the back, just as marked by the dotted lines, but as 'only glass' was inserted, the light rays were nevertheless refracted, if not accounted for. This refraction gives

an altered course to the rays, as marked 'D R,' and explains why the picture at the back becomes shorter from top to bottom, from 'b' to 'd,' but not shortened to that extent crossways from 'b' to 'b b.' The difference is about half the glass thickness of the screen.

"We have, however, several ways to correct this shortcoming, and I think the best way would be to sandwich a colour screen between two right angle prisms.

"One way to correct this shortcoming is to shorten the reflected picture also, which can be done by the interposition of a transparent glass 'T 3,' from 'a c' to 'a b,' as shown in 'Fig. 5.' The acuter and sharper the air prism 'c' 'b' 'a c' is formed between the reflector 'T' and the corrector 'T 3'—that is, the more nearly the reflector T and the compensator T 3 are parallel—the nearer will the reflected picture be in size to the transmitted image.

"We are also able to put such a corrector of the shortcoming at the back of the reflector 'T,' when at the same time such a corrector would be less likely to set up reflections that are not wanted.

"If this corrector or compensator (which can also be another colour screen) at the back, marked 'T 2' is similarly inclined as at 'T' or 'T 3,' then we should shorten the picture at the back still more, and thereby aggravate the defect or shortcoming we wish to compensate or counteract.

"But if we place 'T 2' from 'c d' to 'd,' as shown in 'Fig. 2' (representing here the bottom of the reflector box and not the side as in 'Fig. 1') therefore forming an air prism 'd d' 'd' 'c d' with the acute angle at 'd,' then we shall shorten the picture at the side also, and to balance all the pictures we have only to adjust the back focussing plane.

"Now, with these two correctors placed as indicated (jointly or singly in one reflector box), as shown in 'Fig. 2,' we should have fairly balanced pictures. We have in the glass thickness, however, still a further means of balancing the size of the pictures, because the thicker the glass placed at an angle to the conical light rays, the more will the picture be contracted, therefore smaller, as explained in the foregoing. The focus will also be affected by this interposition of glass and will be put further away.

"The refraction defect, the shortcoming, can also be corrected in a third manner. For illustration, suppose we split the reflector 'T' open at the bottom end, that is the end nearest the lens, so as to cause the refracted light rays at that point to travel a little further between the two surfaces of the refracting substance glass; then we would have all pictures alike, if no other complications would set in. We cannot split glass like

Fig. 6.

Fig. 10.

wood, so we could content ourself by cementing two thin plates together, in such a way as to keep the lower end about half a glass thickness apart, and having the gap thus formed filled up, with transparent material of the same refracting index as the glass in the plates employed, we should thereby really form a prism or a prismatic plate, a wedge. It is, however, much simpler to have an optically worked prismatic transparent reflector, being at the same time a homogeneous glass-reflector coloured in the body or with a red-screen surface. The idea is shown by 'T P'

in 'Fig. 6,' where also the refractions 'D 1' and 'D 2' are given.

"The special form I favour is a reflector box of the shape 'Fig. 10' and 'Fig. 11,' fixed on a collapsible sliding board and camera front and lens front and bellows in front. The plate holders are reversible backs, and would hold the necessary photo—or plate slides—which latter can be interchanged with the blind slides containing matt glass to facilitate focussing. The slides for the back-plateholder can be single or double slides of any make as sold in the market, the plate has only to be pressed accurately against the reflector box to be in register with the focussing line. The negative slides for the top plateholder can also be double or single slides, but must be rather stouter, say 5 to 8mm, as they have to contain for each exposure first, facing the reflector box, a solid blue sensitive plate (an ordinary film to film, a yellow sensitive flexible plate, then some transparent press material, followed by a slide plate (an ordinary photo plate will do) and a slide partition with strong spring

Fig. 11.

to bring the sensitive plates in homogeneous contact when the slide is shut. The here-mentioned flexible plate will be rendered as a reversed negative, and has therefore to be printed through the back.

"There are other systems with two or more reflecting surfaces or reflectors, and as my corrector can be used and is adapted to as many reflecting surfaces as are introduced in a reflector or camera with reflectors, and has then to correct the reflection or transmitted picture or both—that is, has to equalise all pictures to the same size—it follows that I improve the following patents:—Ives 4606<sup>91</sup>, Ives 2305<sup>92</sup>, Ives 3784<sup>93</sup>, Selle 1361<sup>94</sup>, Boulton 15753<sup>95</sup>, Davidson 13468<sup>96</sup>, Shephard 10993<sup>97</sup>, Br 4290<sup>98</sup>, and some others, and not one of these patents points out that a correction is necessary, a correction of a one-sided compressed picture etc, caused through the refraction by the interposition of glass-surfaces at an angle to the light cone. Not a set of colour records obtained from all the above-named patents and which do not compensate the refraction-defect, can, to my mind, be used for the subtractive—that is, the printing method of photography in colours; they can only be used for the additive method that is transparency or chromoscope method, and only if shown again in a similarly constructed instrument." Otto Piennin 105, Hythe Road, Brighton.

COLOUR-PHOTOGRAPHY.—No. 25,908, 1906.—"This invention relates to a box containing mirrors, which divide the light-rays from two centrally placed transparent reflectors, so that two or three photographic colour-records or ordinary photographic negative pictures can be taken simultaneously from one point of view with the aid of two or three lenses, all pictures being of the same size and in the same plane or focussing distance; by reversing the light-rays through the positive colour records and

same instrument a picture in natural colours will be obtained." The claim is:—

"A mirror-box in which one central, transparent, and reflecting screen with two parallel or two prismatically inclined surfaces acts without the aid of a lens as an eyepiece, and transmits the light-rays by reflection, transmission and filtration, through refraction-compensators, so that by the aid of three separate photographic lenses and colour-filters, three negative records in one plane on solid or flexible plate or plates—all from one point of view with one exposure—are obtained, for the additive as well as the subtractive methods of photography in colours and by the aid of the same mirror-box, as explained aforesaid, by reversing the action of the light-rays to render from the colour records a positive, one single picture again, the latter being in natural colours if the necessary colour screens are interposed in the proper places in the path of the light rays." Otto Pienninger, 105, Hythe Road, Brighton.

### New Trade Dames.

CALOR.—No. 293,843. Chemical substances used in photography Johnson and Sons, Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, E.C., wholesale and manufacturing chemists. June 15, 1907.

LAMBEAU.—No. 293,047. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including fluxes for soldering, and not including any goods of a like kind to fluxes for soldering. Jones and Co., 34, Copperfield Road, Bow, London, E., and Triton Chemical Works, Spring Lane, Upper Clapton, London, N.E., methylated spirit makers. May 16, 1907.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Carrying Rodinal.

Rodinal (says a writer in "Photography") is a liquid, and some people do not like carrying bottles of liquid in trunks or suit cases along with clothes; but the dislike comes from not having adopted a suitable vessel for the purpose. That vessel is to be found filled with k for a fountain pen at any stationer's shop. It takes the form of small bottle fitted with a rubber stopper, which is also the teat a pen filler, a glass tube drawn out to a point and projecting into the bottle. In this bottle an ounce of rodinal can be carried, enough develop at least a quarter of a gross of quarter-plates, probably ore. The bottle itself is enclosed in a little wooden case with a new cap, which it just fits, and the bottom of this case inside, having spring underneath it, pushes the bottle up against the cap, as this screwed down, and so both prevents the bottle from shaking about the case, and prevents the stopper from coming out. In this little receptacle—which costs when full of ink 1s., but larger sizes, I lieve, can be obtained—it will be found that the rodinal can be safely carried loose in trunk or portmanteau without the slightest risk of breakage.

KIDDERMINSTER AND DISTRICT PHOTOGRAPHIC SOCIETY.—Mr. W. Weaver Baker, the late secretary of the above society, having removed from the neighbourhood, the secretarial duties will be carried *pro tem.* by Mr. Charles A. Allen, Beulah Villa, Chester Road, Kidderminster, to whom all communications should be addressed till further notice.

PHOSPHORESCENT PAPER.—Referring to the notice *re* above paper page 570 in our issue of July 26, Mr. A. J. Horne, of 97, Bormley Road, Catford, S.E., writes to say that he has now purchased the patent of Messrs. Horne's business devoted to Dr. Balmmain's luminous paint, of which he had charge during his many years' connection with that firm. All orders and inquiries respecting the same could now be sent to Mr. A. J. Horne at the above address.

## Dew Apparatus, &c.

The "Universal" Folding Camera. Made by Louis Gandolfi, of 752, Old Kent Road, London, S.E.

A new camera with very strong claims upon the attention of those who want an instrument of the highest class which they can use for both hand-camera work and on a stand has been submitted to us by Mr. Gandolfi, whose name, long familiar to the trade, is perhaps less so to the retail purchaser, though the firm's reputation for sound, workmanlike instruments of the stand order is one which in times past we have often had occasion to eulogise, and we are therefore favourably impressed beforehand with their new introduction in the form of hand-camera construction. The "Universal" folding camera, we would say at first, is an instrument which permits of lenses from the shortest to the longest focus which in reason would be used upon a plate of a given size. In the quarter-plate camera, which is the size we are now reviewing, the extension is no less than 16in., whilst the camera provides for the focussing of such wide angle lenses as from 2½in. to 3in. The manner in which this short and long extension is obtained is worthy of a separate mention, inasmuch as the facilities provided most certainly conduce to convenient and rapid work. The wide-angle movement of the camera is obtained with a supplementary rack within the rear portion of the instrument, so that nothing further need be done when erecting the camera for use as a wide-angle instrument than the laying down of the projecting baseboard and the raising of the top of the body so as to permit of the movement of the lens panel. This adjustment being made, a supplementary screw on the right of the camera

provides all the focussing which is necessary, and to then adjust the camera for long extension it is merely necessary to bring the baseboard level with the back portion of the instrument, whereupon it clamps itself automatically and forms the runners upon which the camera moves forward. This it does very easily, as the space between the two series of guides is only about ¼in., and the lens front runs from one to the other without any opposition. The full extension is obtained, first, by the rack and pinion, and secondly by a supplementary draw-out extension, which gives the full distance of lens panel to plate of 16in. The triple-extension base is bolted so that, once extended, it cannot slip back by any tension which there may be on the bellows at the longest extension. There is also a catch which automatically clamps the camera at the position of infinity focus on first racking out, which catch can be adjusted for plates or films, or both, as may be desired. A lever, however, is also provided by which the catch is thrown out of action, and when this adjustment is made the front racks forward in the ordinary way without being checked at infinity.

It is in the matter, however, of the rising front that the camera calls for special commendation. By means of two separate movements a total rise of 2½in. in the quarter-plate is obtained. The lens panel rises on the front to the extent of nearly 1in., and the additional rise is then obtained by raising the bellows. The way in which this is done has the very great advantage that the extension of the camera is not affected, nor is either the exact verticality of the front. Swing there is both backwards and forwards, the lens panel being hinged at its base, but the swing can be used as a supplementary motion quite independently of the rising front, and the advantage of having the lens constantly at right angles to the plate and at the same distance from the camera, as the front is raised, is one excellent feature of the camera. In addition to the rising front, there is, as we have first said, a forward and backward swing, with adjustment so that the plate is brought back again at right angles to the base of the camera.

In respect to the other fittings, the camera is provided with level,

reversible finder, and is built square, with a reversing back of unusually solid construction, being faced with brass up to its edges, and thus rendered free from liability to fracture. Throughout the instrument the working parts are metal on metal, a mode of construction which, of course, makes not merely for smooth working in the first instance, but for long resistance to continuous work. The camera submitted to us is intended for use with dark slides, of which three double book-form and of more than the usual depth are supplied. Mr. Gandolfi prefers to make a slide of rather greater thickness than the usual pattern for the sake of the additional safety and light-tightness which are thus afforded, and the same policy of construction for the practical working of the camera is evidenced in many other items of its construction. The whole instrument, we would say, is one to which a critical user of hand cameras can take no exception, and we ourselves have been satisfied that no better instrument of its kind for hand-camera photography and for the most difficult class of subjects for which a stand camera is used could be devised. Its price in the quarter-plate size with three book-form dark slides is £6 10s., including Bausch and Lomb R.R. lens and "Unicum" shutter; without lens and shutter the price of the camera is £5 4s., with three slides.

Sequential Developing Baths. Made by Reynolds and Branson, Ltd., 14, Commercial Street, Leeds.

In this apparatus Messrs. Reynolds and Branson make provision for the requirements of the constantly increasing numbers who for one purpose or another resort to a method of time, stand, tank, or vertical development, as the variants of the system are described by their advocates. The apparatus, which is the result of their study of what is wanted in the way of baths for the plates, has led them to adopt a modification of the old dipping-bath of the wet-plate days. A series of such baths (three or six) they enclose in an outer light-tight case, which, like the separate tanks, is of copper. Each bath accommodates one plate, and is provided with a dipper, also of copper, for raising and lowering the plate. The advantages of such a system in dark-room practice should be obvious enough. The separate tanks permit of one or more plates being undertaken at once as may be necessary, and of alterations being made in the developer of any one if such a course should be necessary. In other words, the vertical-tank method is brought into line with the ordinary methods of the dark-room, whilst, on the other hand, the apparatus is just as amenable to the strict-time, non-inspection method of which there are now many advocates, and which, of course, for the development of panchromatic plates is the most practical method. Chief among the good points of Messrs. Reynolds and Branson's apparatus we regard the safe and rapid

insertion of the plates in the developer. There are no grooves to find, and no possibility of scratching one plate with the corner of another. Apart from the chance of damage which may result in this way, the speed with which plates can be popped into the developer makes for the minimum exposure to the dark-room light, and consequently, as a rule, for the minimum of fog also. This

advantage is worth a good deal, in our opinion, and is to be set against the greater quantity of developer which is needed in "sequential" baths. We would add that the workmanship of the tanks and their appurtenances is of a high standard—of a kind, in fact, which sustains the makers' reputation for turning out articles of the best manufacture. The prices and sizes in which tanks are supplied are as follows:—

	Price.
1-plate, 3 copper baths and dippers, and light-tight box with 4 spaces	s. d. 9 0
Ditto, with 6 copper baths and dippers, and light-tight box with 8 spaces	14 6
5in. by 4in., 3 copper baths and dippers, and light-tight box with 4 spaces	10 6
Ditto, 6 copper baths and dippers, and light-tight box with 8 spaces	18 0
1-plate, 3 copper baths and dippers, and light-tight box with 4 spaces	14 6
Ditto, 6 copper baths and dippers, and light-tight box with 8 spaces	25 0
Other sizes or sets with different number of baths to order at proportionate prices.	

Folding Klito Cameras. Made by Houghtons, Ltd., 88-89, Holborn, London, W.C.

Messrs. Houghtons send us several of a new series of folding pocket cameras which they are at present issuing at popular prices, and for which it is safe to predict a widespread patronage. The cameras of the "Ariel" and other types which owe their origin to the powers of High Holborn, the new Klito series are all characterised by highly compact form and size, yet possess a range of movements which fits them for all the ordinary purposes of hand-camera work. We can say, in addition, that they are soundly and substantially made, and fitted to withstand a good deal of rough usage. We doubt if we can say more in general terms of the merits of the cameras and the prices at which Messrs. Houghton supply them, but it may be well for us to refer to, say, two examples.

The No. 7 folding Klito is a double-extension camera, with extension of 10½ in. from lens to plate, rise of front actuated by a pinion shown on the left in the figure. The infinity catch and

ing scale are made to shift *en bloc* so as to provide for the adjustment of plates and films in the camera, without the confusion caused by an extra scale. There is a square brilliant finder (reversible) as well as bushes for attachment to the tripod. The camera is made to take single-metal dark slides of the very convenient type which is now largely used, but Messrs. Houghton also make a special line of fitting the Houghton envelope adapter, which encloses a focussing screen and hood, and provides at the same time for daylight changing (on the envelope system) of cut films.

ter is certainly the attachment par excellence for a camera to trust from time to time into the pocket, but it is nevertheless instantly interchangeable with a dark slide or other form of plate-holder. The price of the No. 7 Klito, with Busch or Beck R.R. lens, Bausch and Lomb "Auto" shutter, with time, bulb, and instantaneous adjustments, and with two slides, is £3 5s.; with Houghton & Mifflin adapter in place of the slides the price is £3 13s. The No. 2 folding Klito is a single-extension camera which, with single dark slides, sells at £1 17s. 6d., or £2 10s. with the Houghton adapter. In other respects its fittings are on a par with No. 7 instrument, and the bulk is even smaller than that of the latter.

### CATALOGUES AND TRADE NOTICES.

**SECOND-HAND APPARATUS.**—The City Sale and Exchange, of 26 and King's Road, Sloane Square, London, W., send us their latest catalogue of the second-hand apparatus which can now be seen at the West-End branch only. The list includes a large selection of the leading makes of hand, stand, studio, and press cameras, lenses, enlargers, etc., all of which are guaranteed to be in perfect working condition, and are offered at greatly reduced prices. A month's trial of all second-hand apparatus is allowed, and should any article purchased prove unsuitable for the particular purpose required, during that period, the firm will exchange same to the value. The list is worth a careful study by all intending purchasers of any kind of photographic apparatus, and a postcard to the above address will bring a copy by return of post.

**H. CALMELS**, of 150, Boulevard du Montparnasse, Paris, sends its general list of photo-mechanical apparatus and materials, in which it is evident that every description of process work is fully catered for by this Paris firm. M. Calmels also issues a separate list of "Cooke" lenses for process work and of line and screen. Apparatus for colour-photography, plate-sensitization, and other scientific purposes are among his specialties, and a complete set of the various lists issued by him can hardly be of interest to any worker in photo-engraving or allied processes.

**GEKA'S SPECIALTIES.**—The 1907 catalogue issued by the Gekas of Dr. G. Krebs, Offenbach-on-Main, Germany, contains, in addition to its previously well-known goods, several new introductions, chief amongst which we may mention the green, yellow, orange toning baths for use with bromide and chloro-bromide salts, a "Panchromatic" flashlight powder, and the "Hussa" light stand. The last-named, being of simple and practical construction, will no doubt meet a decided want in this direction. Other items contained in the list are too numerous to mention, but our readers can obtain all information by sending an application to the above address, when a catalogue will be sent free and post-free by return of post.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 3.

London Photographic Society. Outing to Kew Gardens.  
High Polytechnic Photographic Society. Outing to Lincoln.

MONDAY, AUGUST 5.

Middlesex Photographic Society. Outing to Fulbourn.  
Living Camera Club. Outing to Amberley, Parham Park, and Wiggonholt Common.

THE "ISOLATION" OF THE MARBLE ARCH, which forms the main object of Mr. F. W. Speaight's traffic improvement scheme, has been decided by the Westminster City Council. The final decision, however, rests with the Borough Councils of Paddington and Marylebone; whilst Mr. Lewis Harcourt, as First Commissioner of Works, has the right of giving the final word of approval or the reverse. Mr. Harcourt has already expressed his sympathy with the scheme of Mr. Speaight.

## Commercial & Legal Intelligence.

**ALLEGED BREACH OF AGREEMENT.**—On July 24, in the Dublin Court of Appeal, before the Lord Chancellor and Lord Justice Fitz-Gibbon, the case of Glover v. McNeill was heard. The appeal was from an order of Mr. Justice Boyd remitting the action to the Recorder of Dublin. The plaintiff claimed to have delivered up a written agreement to let certain premises for a term of five years at the yearly rent of £30. It was alleged that the defendant refused to complete the agreement, stating that he had been induced to enter into it by misrepresentation. The plaintiff also claimed damages for the alleged breach. The premises had formerly been in the possession of a Mr. Bradshaw, who used them as a photographic studio, and it was stated that the agreement was that the premises should be taken over by the plaintiff as tenant to the defendant, and that the plaintiff had purchased Mr. Bradshaw's stock-in-trade, good-will, etc. The defendant alleged that the plaintiff had represented himself as carrying on business as a photographer in St. Stephen's Green and at Upper Ormond Quay, whereas in fact he carried on no such business. The Court reversed the order.

**COPYRIGHT INFRINGEMENT.**—An action was heard at Liverpool Assizes last week, in which Joseph H. Mumford, photographer, of New Brighton, claimed damages against Harrops, Ltd., wholesale stationers, Cable Street, Liverpool, in respect of an alleged infringement of picture postcard copyright. Judgment for plaintiff for £20 and costs on the High Court scale.

**CANVASSING FRAUD.**—At the St. Helen's Police Court last week Edley Des Forges, 61, described as a canvasser, of Fenton Street, was charged with obtaining 2s. 6d. by false pretences from Bridget Burley. It was stated that for some time prisoner had been employed as a canvasser by Messrs. Taylor, photographers, but he was not authorised to collect any moneys. On June 10 he called on Mrs. Burley, who lives in Raglan Street, who was paying instalments towards the cost of an enlarged photograph. He asked for her card, and collected from her sums amounting to 2s. 6d., which he marked in the book with initials other than his own. On the last occasion that he called he promised to let her have the enlargement by the following Monday. Subsequently from what she heard she went to see Messrs. Taylor, and information was given to the police. When prisoner was arrested he remarked, "I have been a fool." Before he was apprehended prisoner returned the 2s. 6d. to Mrs. Burley, and asked her not to say anything about it. Prisoner admitted that he got the half-crown, but said the money would have been deducted from his wages at the week-end. He was sorry for what he did. He was fined £1, or fourteen days' imprisonment.

**A TORQUAY BANKRUPTCY.**—The first meeting of the creditors of William John Wilkinson, photographer and picture-frame maker, 101, Union Street, Torquay, was held at the offices of the Official Receiver for the Exeter District on the 25th ult., before the Official Receiver. The summary of accounts showed liabilities expected to rank at £84 6s. 10d., and the assets £40 9s. 2d., leaving a deficiency of £43 17s. 8d. Causes of failure alleged by debtor:—Bad trade caused by bad season, competition, and pressure by creditors. The Official Receiver observed that debtor commenced business about two and a quarter years ago with a capital of £14 of his own and £25 borrowed from his mother. He purchased a business for £50, on which a balance of £15 was still owing. The takings were estimated at about £4 per week, the business expenses 30s. a week, and household expenses 35s. a week. Debtor, who was represented by Mr. Greenfield, of Torquay, subsequently underwent his public examination at the Castle of Exeter, before the Registrar (Mr. John E. Daw). The debtor was allowed to pass.

**NOTICE OF REMOVAL.**—The Lumière N.A. Co., of 4, Bloomsbury Street, W.C., announce that on August 1 next they will remove their offices to larger and more commodious premises at 89, Great Russell Street, London, W.C. (next the British Museum), to which address all letters and communications should be addressed on and after the above date.

## News and Notes.

MR. W. H. HOLLIDAY, photographer, of Jewry Street, Winchester, died last week after a long illness. Mr. Holliday went to Winchester from Southampton twenty-six years ago, was assistant to Mr. Rider for three years, and then started a business on his own account, which he continued up to the time of his death.

**OIL PRINTING DEMONSTRATIONS.**—Owing to the keen interest taken in the Rawlins oil printing process, Messrs. J. J. Griffin and Sons, Ltd., have increased the number of weekly demonstrations, which are now given on Tuesday afternoons at 3.30 and Thursday mornings at 11.30, at their rendezvous, Kingsway, London, W.C.

**PAGET CASH PRIZE COMPETITION.**—We would again draw our readers' attention to the above competition, as, although the closing date is not until January 31, 1908, it is by no means too early to begin to secure their negatives, and the holiday season brings to many practically the only opportunities they have during the year to obtain suitable subjects. There are a number of prizes to be awarded in each of nine classes, and "Paget" materials must, in all cases, be used. Full particulars and rules may be obtained on application to the Paget Prize Plate Co., Ltd., Watford, Herts.

**LUMIERE COLOUR PLATES.**—Mr. Jonathan Fallowfield writes that, although his stock order for the above plates was placed at the first intimation of their being on the market, Messrs. Lumière and Co. now advise him that, owing to the great demand, it will still be two or three weeks before they can execute English orders, and it is anticipated that even then the demand will be considerably in excess of the supply. Mr. Fallowfield therefore wishes to assure those customers who have placed orders for these plates with him that all orders will be executed in strict rotation as soon as the first consignment is on the English market.

**FOUND IN St. James' Park** on Sunday, July 21, a parcel of photographs containing one specimen of "Ozobrome," one specimen of "Metalotype," three specimens of "Argo" paper, one bromide enlargement 12 x 10, and four photogravures of a wedding group. The owner can obtain same by applying to Messrs. Ozobrome, Ltd., 96, Prince of Wales Road, Kentish Town, N.W.

**THE West of England Manufacturers' and Industrial Exhibition, 1907,** which includes a section for photography, will be held at Plymouth from November 5 to 27. In the photographic section there are eleven classes, all open to the United Kingdom, in each of which a silver shield, bronze shield, and diploma will be awarded, with the addition of a gold shield in the "champion" class. A number of special prizes, to which various conditions are attached, are also offered for competition. The judges will be Messrs. F. J. Mortimer (Editor of "The Photographic News") and Walter Finch. Entries close October 5. Full particulars and entry forms may be obtained from the secretary, Mr. A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.

**THE WET COLLODION PROCESS.**—We are in receipt of a pamphlet from the School of Photo-Engraving and Lithography, Bolt Court, giving the instructions to students at this institution for the working of the wet-collodion process. The pamphlet includes all the necessary formulae, with a number of half-tone reproductions explaining the manipulation and illustrating also the most common defects and markings which are liable to occur in practice. We presume that the pamphlet is not issued to the public, but is for the instruction only of the students in the school.

**INCANDESCENT ILLUMINANTS.**—In the course of a lecture on the above subject at the Royal Institution, Mr. James Swinburne said that the electric incandescent light is undergoing a great change. Carbon is being replaced by metal wires. It has been found possible to make wires of high enough resistance of tungsten, osmium, tantalum, and a few other metals and compounds. The osmium lamp was the first of these, but there was difficulty in making it of high enough resistance. The tantalum lamp is now in great demand. It is made for 100 to 130 volts, and is much more efficient than the carbon lamp. It will not last long on alternating currents, however. The wires of a lamp that have been run for some time on a direct current show a curious notched or crinkled appearance under the microscope.

But a wire that has been run on an alternating circuit looks like the metal had been melted into short cylinders with round ends. These cylinders had stuck together end to end without their being in a line. Sometimes the little cylinders are nearly separated, merely touching at a corner. This action is very extraordinary, has never been explained. In addition to this, when a lamp is down on an alternating circuit, the wire sometimes goes all over and sometimes it breaks in several places, and tangles itself up in an extraordinary way; at other times it breaks up into numerous pieces, which will be found lying on the inside of the globe. One of the other lamps showed a change under the action of the current, but it is not so marked as in the case of tantalum. One of the interesting of the new lamps is the Zircon. It is said to be made of zirconium and tungsten, and lamps of this material have been made for 200 volts, a matter of the greatest importance from a distribution point of view. It is possible that the conductor is really a zirconium of tungsten, and this opens up a new series of compounds. A Zircon lamp for 100 volts has really six separate loops of wire mounted in series inside a bulb. A recent improvement is to provide a tremendously light spring for each loop, so as to keep it taut. The lamp can then be used in any position. Tungsten seems to be the favoured metal, as it gives a very high efficiency. It is probable that the future will have an efficiency of nearly a candle per watt. This is promised by the use of tungsten. At the same time it must be admitted that to make a wire with a resistance of 500 ohms enough to give 20 candles with 20 watts is a triumph of invention.

**"PHOTOGRAPHY AND THE PRINTING PRESS."**—A reprint of lectures delivered by Mr. Charles W. Gamble to the School of Photography, Manchester, for the Royal Scottish Society of Arts, has been reprinted by this body, which has its headquarters at 117, Colinton Street, Edinburgh. Mr. Gamble's lectures supply an interesting and readable review of the modern methods of photo-mechanical printing, and on that account are quite of general interest; the latter part dealing with some of the more recent innovations in process will be sufficiently technical to supply information to the practical photographer.

**THE TRAILL-TAYLOR LECTURE.**—On Tuesday, October 22, at the New Gallery, Regent Street, W., the tenth Traill-Taylor Memorial Lecture is to be delivered by Mr. S. D. Chalmers, M.A. The subject will be "The Aberrations of Photographic Lenses."

**THE PLAYERTYPE PROCESS.**—In reference to an answer to a correspondent, on page 512 of a recent issue, Mr. S. C. Puddy writes, enclosing a number of altogether excellent copies of black and white line drawings, woodcuts, etc., made by the Playertype process. These specimens, he tells us, were made by daylight, artificial light having proved not quite so satisfactory. The negatives were made on Ilford gaslight paper, and the positives are on the same. On Paget Gravura and self-toning P.O.P., and on Ilford P.O.P. results in these different materials being fairly equal in quality. The process is evidently of occasional service in the hands of a competent worker, and we may refer those interested to the account of the Playertype process in the 1906 "Almanac," p. 801.

**WHAT IS GELATINE?**—According to the "Chemist and Druggist" in its issue of July 27, a good deal of the lower grades of gelatin on the market is badly contaminated with either arsenic or copper. The former is derived from the pyrites used for the preparation of the sulphuric acid used in manufacturing gelatine, while the latter is derived from copper utensils. The following details from samples recently examined by a London analyst are of interest.

Three samples contained 3 to 5 parts of arsenious oxide per million.

Two samples contained 5 to 10 parts of arsenious oxide per million.

One sample contained 13 parts of arsenious oxide per million.

Three samples contained 0.3-0.5 grain of Cu per lb.

One sample contained 1.25 grain of Cu per lb.

"THE BULLETIN OF PHOTOGRAPHY" is to appear as a weekly journal of professional photography from the offices in 606-608, 8th Street, Philadelphia, of our contemporary, "The Camera." Frank T. Chambers is to be the managing editor. The first issue is announced to appear this week.

THE PORTRAITS IN EDINBURGH.—The old story of an enlargement being told to the Edinburgh householders, as we hear from a letter in the "Evening Despatch" of that city, which is as follows:—

The writer wishes to warn all householders of several men who are coming to the city requesting photographs to be copied, and that they will give an enlargement or coloured copy free of charge. The only stipulation they make is that the photograph is hung up in the drawing-room, or parlour, as an advertisement so that it may be seen by any friends who come to the house. They return with the enlargement, or coloured photograph, in any case may be, they demand a certain price to cover the cost of the frame, and if this is not paid to them they refuse to return original photographs.

The writer hereby warns the public that practically all these photographers live by misrepresenting the actual conditions under which they are working, and by refusing to return the original until they extort the money for a frame, the price of which is many times more than its value. The simplest way to put a stop to this is to refuse to have anything to do with such people, and to give their orders to people who have established businesses in the

city. We are glad to see the provincial Press still assisting in the work of enlightening the public as to the real character of this business.

THE HOLIDAYS: WHERE TO STAY AND WHAT TO SEE," is the title of a bulky volume published by Walter Hill, 67 and 69, Southampton Row, London, W.C. It contains copious lists of seaside, farm- and country lodgings, hotels, boarding-houses, etc., in the districts served by the Midland, London and North-Western, Great Central, Great Eastern, Great Western, and Great Central Railways, together with a quantity of useful and interesting information for the holiday-maker regarding the chief places of interest in the various districts, illustrations, maps, etc. The first part is entitled "Where to Stay in London," and this should be of interest to visitors from the provinces or from the colonies abroad. The book is obtainable from the railway bookstalls or from the publishers, price 1s., or 1s. 6d. post free from the publisher.

VELOX COMPETITION.—The fourteen prints which won prizes in the "Velox" competition are now on view in the Exhibition at Messrs. J. J. Griffin and Sons, Ltd., Kingsway, W.C., and are well worth a visit to see. The exhibition is a most successful and a most interesting one, and a most successful one.

THE FIRE BROKE OUT ON JUNE 23 ON THE PREMISES OF MESSRS. DENNISTON AND ALLAN'S PHOTOGRAPHIC AND STATIONERY STORE AT NANKING ROAD, LONDON, E.C. The fire broke out on the energy of the fire brigade the blaze was put out on the floor on which it originated, and serious loss thus resulted.

RESPONDENT ASKS FOR THE NAME OF PUBLISHERS OF FIGURE STUDIES WITH THE TRADE MARKS OF B.N.K. (enclosed in a triangle) and asks for those able to supply the information will address "The Editors," care of the Editors.

SENSITISERS.—Mr. Arthur Payne, in his new book, "The Collodion Process," says:—"It may be of interest to mention that we have found pinaverdol, orthochrome T, pinachrome ethyl purple 6B, cyanine, pinacyanol, and dicyanin, to be the best sensitisers when applied to collodion bromide films. A weak solution of 1 in 50,000 parts alcohol is flowed over the plate for about two minutes, and after washing the plate under the water for two to three minutes it is drained and exposed in the sun. Plates prepared with any of these dyes may be safely developed in a fairly powerful green safelight, as they appear to be very insensitive to green when used with a collodion film. The plates work very clean, and may easily be developed with a pinone developer, or probably any alkaline developer, which is best suited to suit these plates. My experiments lead me to think that pinacyanol will prove to be the best red sensitiser for collodion bromide plates, as the plate is more sensitive to the red than to the yellow, when both are of equal luminosity, and exposed to the yellow enclosed arc light. I am somewhat disappointed with the use of dicyanin, when used with a collodion plate, as I expected a very high red sensitiveness; while, as a matter of fact, it does not appear to be such a good red sensitiser as the previous dye, and the red and blue are of equal sensitiveness when exposed under the same conditions, and the general sensitiveness of the plate is not so good as what is obtained with pinacyanol. Dicyanin is

closely followed by ethyl violet and ethyl purple 6B, both of which give excellent results under favourable conditions." In connection with the above, it would be as well to draw attention to the fact that Mr. Payne describes in the above-mentioned book an easy dry collodion process which should be of considerable value in colour work.

## Answers to Correspondents.

\* \* All matters intended for the text portion of THE JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. Ralston, 259, Sauchiehall Street, Glasgow. Photograph of South African Cricket Team and an Eleven of Scotland.

J. Yeoman, Photographer, Bedale, Yorks. Photograph of the Wesleyan Choir, Bedale.

Albert William Sargent, 12, Albany Road, Cardiff. Photograph of the King accepting an Illuminated Address from the Lord Mayor of Cardiff. Photograph of the King reading a Reply to Address at City Hall, Cardiff.

G. L. McKeggie, 513, Union Street, Aberdeen. Wash Drawing of Marischal College, Aberdeen.

J. F. Duthie, 13, South St. David Street, Edinburgh. Photograph of Group at Edinburgh Motoring Club Hill Climbing Competition.

Henry George Summers, 33, Church Street, Calne, Wilts. Two Photographs of King Edward's visit to Calne, Wilts. on July 22nd, 1907.

Elisha Porigo, 44, Prince Albert Street, Oldham. Photograph of 6 score 5 lbs. Wrestling Championship of the World, between W. Collins (Oldham) and J. Fahy (America).

William Muntz, 8, Leyland Arcade, Southport. Photograph of Miss Ethel Carnie, three-quarter length.

PHOTOGRAPHIC RIGHTS.—Would you be kind enough to let me know, through your columns in the "B.J.," whether the vicar or churchwardens have power to stop me from printing on postcards and selling a photograph of the interior of the parish church that I have taken?—POSTCARD.

They have none at all; you are at liberty to issue the photograph.

W. W. WALL.—We can only advise you to be guided by your solicitor.

STEREOSCOPIC NEGATIVES.—I have a new stereo camera, fitted with Zeiss Tessar lenses, and have just developed my first two dozen plates. In every instance one picture on the same plate comes up in the developer before the opposite picture, and also shows more contrast. Also, when I come to print from the negative one side of the transparency print is much more brilliant than the other. I have had the camera back to Messrs. —, and they returned it as all right, and also sent me four negatives of street scenes, which seemed to be evenly developed. Could this fault, mentioned above, be due to causes outside the lenses, and if so, what are the causes?—P. C. SMITH.

Many things other than the lenses may be the causes, though it is rather improbable that anything but the lenses should give the greater density so uniformly, as has been your experience. However, we have so often found an almost incredible explanation to be the right one after all that we suggest a tilted developing dish or the unequal access of the dark-room light to the plate (causing slight fog on one part only), as possible causes. We ought to see the negatives to say positively.

PANORAMIC CAMERA.—Can you inform me if there is a panoramic camera on the market, with a lens fitted to work on a pivot automatically on exposure being made, thereby making a picture covering nearly 180 degrees? The arrangement causes the lens

to move from side to side, the centre being pivoted, the front and back move in opposite directions, so that picture is taken as by one sweep of a brush. If so, who are the makers, and what is the lowest price?—T. E. (Sierra Leone).

The Panorama Kodak (Kodak, Ltd.) is sold in two sizes—7 x 2½ and 12 x 3½ inches—at £2 10s. and £3 10s. The Al Vista (Houghtons Ltd.) is sold in four sizes—3½ x 9, 4 x 11, 8 x 12, and 5 x 16, these being the maximum size of picture, though short lengths may be taken. Prices from £4 4s. to £10 10s.

**DUFFER.**—(1) If the negative be of a suitable soft character there is no difficulty at all in obtaining all the gradation even in an enlargement on a much larger scale than you suggest. (2) There are none. The lens you name used, say, at f/8, for the projection of the negative will give fine definition to the corners of the latter.

**A. BUNKER.**—Better apply to the Tress Company, 42, Oxford Street, London, W.

**EYE TROUBLE IN RETOUCHING.**—When retouching I am very much troubled with my eyes. I cannot see clear. I have been told that I am troubled with astigmatism. I have had my eyes tested by a good local eye-tester, but the test applied I do not think is the right test for retouching. It might be all right for reading and seeing in general, as the spectacles I have got benefit me in that way; but yet they seem to be wanting in correcting a defect. When retouching a kind of glare comes over the eye then, and I can see nothing, and my eyes water a little. I feel sure, if glasses could be made to get over that, and slightly magnify, it would not hurt my eyes at all, I feel sure. I can read the test of large and small letters almost at any reasonable distance; I can also distinguish colours; straight lines drawn at various angles puzzle me slightly more. I can see things better farther away than near to. This is where the mistake comes in the test, I think. They test for ordinary everyday matter, instead of in a retoucher's case, for close small effects to stop the glare. (1) Can I get a pair of glasses that will get me over the difficulty? (2) Where? (3) Price?—J. COOK.

You ought to go to the eye hospital at Liverpool or Manchester and have your eyes properly tested by an ophthalmic surgeon, and get a prescription for the glasses. The hospital price of the astigmatic glasses is 7s. 6d.

**PRISMATIC DISPERSION COLOUR PROCESS.**—Will you tell me whether the process of colour photography by prismatic dispersion, outlined in your supplement of March 1, has reached a practical stage? There is something attractive in the idea of dispensing altogether with dyes, etc., and letting the prism form the colour. I submitted the article in the "B.J." for March 1 to Messrs. Penrose and Co., but they did not seem inclined to take up the matter seriously; nor, I think, could Messrs. Sanger-Shepherd and Co. If any results are to be done, or if any firm is prepared to produce the apparently simple apparatus required to adapt an ordinary camera in the process, I should be glad to know.—(REV.) J. M. JEAKES.

So far as we are aware, no one has yet placed on the market the necessary apparatus, but there should be no difficulty in setting up the arrangement. A single line screen is required, with the opaque lines wider than the transparent; this could probably be obtained from Griffin and Sons, Ltd., Kingsway, as they are agents for the Schulze screen, which is of this character. A low angle prism can be obtained from Penrose and Co., 109, Farringdon Road. These are supplied for cementing to the face of Lippmann heliostrophes. This would probably give quite enough dispersion, as the length of the spectrum could be adjusted by variation of the distance between prism, screen, and plate.

**E. FOX.** Amidol is the hydrochloride of diamidophenol. Its formula is:— $C_6H_3(OH)NH_2NH_2$ .

**STUDIO.**—Can you advise as to the best way to glaze a new studio—what glass, putty, paint, etc.? North light, wooden astricals.—B. J. P.

For the sides there is nothing better than ordinary plain glass. If the studio is overlooked by neighbours, fluted glass would, however, be better, as that cannot be seen through. For the roof, what is known as "rolled plate" (white) is good, as, by reason of its thickness, there is no risk of its being broken by

hailstones. Putty made with good linseed oil is best for purpose. For the paint, any quiet unobtrusive colour would suit.

**REGISTRATION OF NAME.**—Would you kindly let me know how to register a name for trading under—i.e., The ——— Photo Company?—E. F. TOBIN.

The registration must be effected at the Patent Office. Write to the Comptroller, Patent Office (Trade Marks Branch), 25, Southampton Row, W.C., enclosing a penny stamp, you will be forwarded full instructions as to the procedure for the registration of trade marks, names, etc. No charge is made for instructions.

**COPYRIGHT.**—I shall esteem it a favour if you will kindly let me know whether a photographer has the right to exhibit a reproduction of my work in his case or shop window in any shape or form. The law as it stands gives a client the right (on payment of a fee) to have them reproduced by anyone, but if it is the right to another to show as his work the law certainly need of some amendment as regards copyright. Thanking you in anticipation for a reply in this week's journal.—W. M.

The photographer has no right to make or exhibit a reproduction from a negative made to the order of his customer, unless the latter's permission. The fact is constantly disregarded, but it nevertheless can be enforced by a sitter.

W. E. M., and others.—In our next.

**STIFFENED PRINTS.**—I have an order for some 12 x 10 unmounted photographs, which have to be enamelled and stiffened to the thickness of a postcard. I think I once came across instructions for doing this kind of thing in one of the "Almanacs," but have not been able to find them. I should be greatly obliged if you will inform me how to go about it.—ARISTO.

The usual plan is to squeeze paper to glass or ground glass when half-dry attach a backing paper of the necessary thickness and strip the whole off when dry. In short, the usual method for glossy prints.

**PLATINUM TONING.**—I should be much obliged if you could give me by answering the following:—1. Is the tone obtained by acid-platinite bath used for matt P.O.P. permanent? 2. Can you give me a formula suitable for most brands of paper? 3. What is the order of mixing and its keeping properties when mixed? How much washing is necessary between toning and fixing?—CHLOROPLATINITE.

1. The prints have great permanence, though not quite so good as those toned with gold and platinum—that is, general experience, and the two baths are usually recommended for this reason, as well as for the blacker tones. 2. Chloroplatinite, 4 grs.; phosphoric acid (sp. gr. 1.12), 2 oz.; water to 20 oz. The makers' formula may usually be used to be the best. See the "Almanac." 3. The bath will almost indefinitely before use, but not well afterwards. 4. At least half an hour before use as soon as made. 4. At least half an hour before use as soon as made. A bath of bicarbonate of soda (1 oz. in 10 oz. of water) is advisable half-way through the washing to destroy all traces of acid.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographers' Association of Canada, at a recent Convention, shown its interest in current business problems. (P. 591.)

correspondent draws our attention to a convenient method of ing a studio. (P. 606.)

ome descriptions of studio premises installed by the Eastman ak Company are given on page 599.

we suggest for discussion the liability of the canvassing photo- her to come under the Pedlars Act, under which a licence is ired, and must be renewed when the licensee removes to a fresh ict. (P. 590.)

the advantages of gum arabic as a mountant are the subject of e notes on page 590.

three-colour carbon prints, screen plates for one-exposure colour yography, and a new type of magazine camera, are among the nts of the week. (P. 603.)

r. Harry E. Smith, in a recent paper, discusses the composition e bromide print after toning by the sulphide process. (P. 594.)

the practice of a clever exponent of night photography, Mr. Robert es, as communicated to the Edinburgh Photographic Society, ars on page 596.

photography as an art cannot by any possibility be expected to ft from a new work on the subject reviewed on page 605.

major-General Waterhouse draws attention to the early reference 2) to the focal centre of a thick lens. (P. 602.)

the last of Mr. Foxlee's articles on the wet collodion process s with collodion positives and with possible causes of failure t wet collodion. (P. 592.)

## EX CATHEDRA.

### Spurious Old Pictures.

There is very little doubt that at the present time a good number of spurious "Old Masters" are being produced, many of which find their way, at high prices, to America—so it is said. One day last week the "Evening News" gravely informed its readers that there is a studio in the West End of London where "Old Masters, and pictures by eighteenth-century masters," are made to order, and professes to explain how the work is done. The method, we are told, is as follows:—Old canvases or panels are procured, the paints are made from old receipts, and the subject is painted in the style of the selected master. After the painting is finished, it is allowed to stand for some days exposed to the dust of the studio. It is then given a thin coating of Vandyke brown varnish and dusted over with a sprinkling of floor-dust. After this another coating of varnish is put on and allowed to dry. Finally the picture is put into an oven and well baked. This is to strain the canvas, and so give the necessary cracks to the paint. Here, then, is, according to our contemporary, the whole secret of the method of manufacturing spurious Old Masters; but there is nothing said as to the painting being done by skilled painters, who are quite familiar with the style of the particular master, and who are fully capable of doing the work. As a rule, people do not pay a large price for an Old Master without having the opinion of an expert as to its genuineness; and we very much doubt if one would be deceived by a picture faked by this method. Still, the fact remains that there are many spurious old pictures in existence, whether done by this method or any other.

\* \* \*

### The Photographers' Association of Canada.

For the first time during the past few years the annual Conventions of the Photographers' Association of Canada were revived, and during the latter part of last month two days were devoted at Toronto to meetings of professional photographers interested in the progress of their craft in Canada. There is no intention, we are told, to allow the annual function to fall again into abeyance, and evidently from the prospectus of the Convention the Association contains within itself all the elements necessary for such an annual occasion. As our report shows, the meetings were devoted strictly to the business and technical topics of the professional photographer, and if the Convention devoted some part of its brief two days' session to the social side of its activities it cannot be blamed for doing so, inasmuch as its plan of campaign involves the first principle "that the other fellow is a decent chap when you get to know him!" We wish the Association and its members all renewed prosperity.

### Gum Arabic as a Mountant.

If the photographic world were canvassed as to the mountant used for mounting pictures, one might fairly speculate that something like ninety per cent. of the replies would refer to starch. There is no gainsaying the fact that no better material exists for the purpose, as it has no deleterious action on photographic prints. In saying this, we are not considering the different commercial mountants that have, during the past few years, been put upon the market. They are very convenient in use and keep well, but as they are all, more or less, secret preparations, we can say nothing further about them. Starch paste, however, must be used the day it is made, or the day after, otherwise it becomes watery and loses its adhesiveness. Many correspondents have, from time to time, written us complaining that to make a fresh paste of starch each time that a few pictures have to be mounted is troublesome, and asking how that can be avoided, etc. But the small amount of trouble involved in making a little starch paste as required is quite trivial, yet is evidently a consideration with some. Hence we may recommend as a very convenient mountant the simple solution of gum arabic, much used in times past. Of late years, however, it has obtained a bad reputation, but we doubt if there is any actual foundation for suspicion. We are led to this consideration by being shown, within the last few days, a portrait print, mounted in the year 1857 with gum. The print was toned in the old combined bath universally employed in those days. The picture showed no signs of fading: all the delicate tones were perfect: the high-lights, it is true, had a slight yellow tinge, but it is quite conceivable that they were not actually white in the first instance. This fifty-year-old picture is a conclusive proof against the prevailing idea that prints mounted with gum must necessarily fade, and, indeed, such a conclusion is not warranted by the properties of gum arabic, which is a neutral substance, and not an absorbent of moisture, like gelatine and some other bodies. When a solution of it is evaporated—as when the mounted print is dry—the gum remains in its original condition, and has no affinity for moisture. As to why gum is now in such bad repute, the cause is not far to seek.

\* \* \*

### Gum Mountant to Keep.

A solution of gum, if kept for long—a week or two, particularly in hot weather—is more or less decomposed, becomes mouldy on the surface, acquires a sour smell, and becomes acid. If used in this condition there need be little surprise that photographs mounted with it do eventually show signs of change. This decomposition, however, may be entirely avoided by the addition, after the gum has been dissolved and strained, of an antiseptic—say six or eight drops of carbolic acid, or a similar quantity of oil of cloves, to half a pint of the solution. With this addition the solution will keep good for many weeks, and is always ready for use. It is not necessary that an expensive gum be used; a fair sample of Senegal gum, which at the present time is sold at the oilshops and by drysalters at about a shilling, or a trifle more, per pound, is quite suitable for the purpose. One thing that has probably brought gum into bad repute is the use of what is termed “office gum,” as sold by stationers. This in many cases contains but little gum, and that of the commonest kind. It is almost always acid, and we are told that the antiseptic sometimes used is the bichloride of mercury. If such stuff as this is used for mounting photographs ill effects must be anticipated. But with a fresh solution of gum arabic no ill results need be feared. The conveniences of a solution of gum are that it is always ready for use, and if a print is required to be taken off the mount, it is readily done by soaking it for a short time in cold

water. This is not the case with starch or most other mountants. With some it is very difficult to remove the print at all without injury.

### ITINERANT PHOTOGRAPHERS AND THE PEDLARS ACT.

SEVERAL times of late we have had cases come before us in which the question has arisen as to whether a photographer who goes about taking views and portraits which he very shortly supplies to his customers, comes under the Pedlars Act, whereby a licence is required. One correspondent writes us that he went about taking photographs of residences, and afterwards submitted the photographs to the owners, and solicited orders for them. For doing this the police had threatened him with proceedings because he was not possessed of a pedlar's licence. In our issue of the 12th ult. a brief report was given of a case where two persons were brought before the Blackpool Police Court, charged with peddling without a licence. It appears they were going from door to door with a camera asking if the occupants would have their portraits taken. As the Chief Constable did not press the charge, the defendants were dismissed on their paying the costs. In the same issue we reproduced a copy of a circular that a correspondent had sent us that had been left at his house, the purport of which was that the firm—a very important one according to its own showing, though no address was given—had received instructions to photograph certain houses and premises in the district. To give pictorial and artistic effect to the photographs the occupants and their children were invited to stand outside at the time the people would be at work. Proofs, it was stated, would be shown in a day or two. Of course, when the latter were shown, an order was solicited.

A point of some importance is: Do these people come within the Pedlars Act? By 22 and 23 V., c. 36, a hawk's licence was not required by the maker or worker of goods who carried them abroad or exposed them for sale. This Act, however, was repealed by the Act of 1871—the one now in force. By this Act a pedlar is not allowed to hawk goods of his own make without a certificate. We here quote from the Act the definition of pedlar. “The term ‘pedlar’ means any hawker, pedlar, petty chapman, tinkler, caster of metals, mender of chairs, or other person who, without any horse or other beast bearing or drawing burden, travels or trades on foot and goes from town to town or to other men's houses, carrying to sell or exposing for sale any goods, wares, or merchandise, or procuring orders for goods, wares, or merchandise immediately to be delivered, or selling or offering for sale his skill in handicraft.” Although no reference is made to photography or photographs, it would seem that the last line would include them, and apparently this was the view taken in the case cited above, at the Blackpool Police Court. It may be mentioned also that under the Act certain classes of vendors are exempt from the need of a licence, viz.: “(1) Commercial travellers or other persons selling or seeking orders for goods, wares, or merchandise to or from persons who are dealers therein and who buy to sell again, or selling or seeking orders for books as agents authorised in writing by the publishers of such books; (2) sellers of vegetables, fish, fruit, or victuals; (3) persons selling or exposing for sale goods, wares, or merchandise in any public mart, market, or fair legally established.” In the exemptions, again, there is no reference to photography or canvassing for photographers. Up to the present we have heard of no photographer's canvasser being prosecuted for not possessing a pedlar's certificate, though, perhaps, according to the strict reading of the Act, he requires one.

one point is one which may certainly arise again in connection to the cheap class of travelling canvasser-photographer, and it may be found that in the restriction of the Pedlars Act may be found some means of handicapping gentry whose methods of business must be both disful and harmful to photographers established in a not large way in provincial towns. In our reading of the words "selling or offering for sale his skill or handicraft" are clear enough, and with them before us cannot see any distinction between the photographer the tinker or chair-mender, except that the two latter usually better craftsmen than the travelling photographer, and frequently carry on their business in a manner open to suspicion. We should be interested in hearing of any police-court cases which may come up in this connection, and perhaps any reader in whose town one is interested will send us the newspaper report of it. In the meantime, it will be of interest if we mention one or two regulations of the Pedlars Act, from which it will be seen that the obligation on a travelling photographer to obtain a licence before he can ply his trade, would have a very salutary effect in limiting the operations of the travelling canvasser with his camera.

A pedlar's certificate may be obtained from the Chief Officer of Police of the district in which the pedlar is at work, provided he, or she, has resided in that district for one month, and the applicant is a person of good character, in good faith intends to carry on the trade of a pedlar. A certificate is, however, not granted to any person under fifteen years of age. The charge for a certificate is 5s., and it is only available for the district for which it is issued. However, the holder of a certificate can have it

endorsed by the officer of another district in which he desires to trade on the payment of sixpence. The duration of a certificate is for one year from the time it was granted. A pedlar at any time must produce and show on demand his certificate to any constable, or to any person to whom he offers his goods for sale, or any person in whose private grounds or premises he is found. He is also to show the contents of his pack to any constable on demand. In the case of a conviction for any offence, the magistrate can endorse a pedlar's certificate, or deprive him of it altogether. From the above it will be seen that the law is very stringent with regard to pedlars. But, as a rule, magistrates usually take a lenient view in the matter if they are convinced that the pedlar has no dishonest intent.

Since the above was written we have been interested in noting, in the report of the Convention of the Photographic Association of Canada, the headline: "Death to the Coupon Pedlars." This form of cheap competition is evidently just as harmful to reputable business in the Dominion as it is here, and though we are not acquainted with the terms of the Pedlars Act which is in force in Canada, we are glad to find corroboration of our suggestion from a remark by the treasurer of the Association: "These men are undoubtedly pedlars, and if we could compel them to get a licence costing twenty-five dollars we could soon freeze them out." The status of the travelling photographer in reference to the Pedlars Act appears to be worth the attention of a body such as the Professional Photographers' Association, which has consistently shown its readiness to advance the interests of the profession.

## THE CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF CANADA.

After being in a state of coma for about ten years, the Photographers' Association of Canada revived last year, and this year held their annual convention, meeting in Toronto July 24 and 25.

The gathering in numbers, enthusiasm, and interest was very successful, repaying those who had worked hard to make it so. The establishment of an employment bureau, whereby members could secure helpers and helpers situations without fee, was the first of the report of a special committee dealing with the situation.

The matter of copyright on photographs in Canada was referred on by another committee, and their report adopted. It was recommended that representations be made to the Dominion Government to revise the Copyright Act in such a way that no mark or lettering would be necessary on a copyrighted photograph, or, failing that, to have the least possible amount of marking or mark thereon necessary to indicate its registration. The present lengthy formula in many cases seriously detracts from the pictorial value of the photograph. Also to have the present fee of one dollar reduced to fifty cents for each subject. A practical talk on lenses was given with illustrations by Mr.

S. Lawrence, of the Bausch and Lomb Company of Rochester, New York.

Mr. W. S. Lively, president of the Tennessee School of Photography, graphically demonstrated how he had made some very successful pictures in a variety of lightings by the "Aristo lamp."

There were demonstrations in lighting and posing by some of the most successful operators in a number of the city studios, and demonstrations in the convention building by different plate and paper manufacturers.

The visitors were entertained by the local manufacturers and dealers in the evening with a trolley ride around the city, ending with a dance and supper at Sunnyside.

The officers for the ensuing year are:—A. M. Cunningham, Hamilton, President; J. Frank Jackson, Barrie, First Vice-President; John Kennedy, Toronto, Second Vice-President; Frederick Roy, Peterborough, Third Vice-President; E. Poole, St. Catharines, Secretary; Charles L. Rosevear, Toronto, Treasurer.

Toronto was unanimously decided on as the place of meeting for 1908.

**HOUGHTONS' QUARTERLY.**—The current or summer number is devoted to the consideration of apparatus specially suited for holiday work, including the new series of folding "Klito" cameras, which, being compact in form and easily carried in the pocket, should prove considerable value to tourist photographers and others to whom bulk and weight are serious considerations. Messrs. Houghtons

also make a special offer to all readers of the "Quarterly" who are not yet users of "Ensign" roll films, whereby a sample spool may be obtained at a considerably reduced price. The special sample coupon issued for the purpose must be correctly filled in and sent, together with the necessary stamps, to Messrs. Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

## THE WET COLLODION PROCESS IN PRACTICE.

[The following article, which concludes the course of instruction in wet collodion which has appeared in our columns some weeks past, deals with the application of the process to positives on glass or to ferrotype. The whole series of chapters has aimed at giving concise practical directions in the practice of a process which for certain purposes is unsurpassed.—Eds., "B.J."]

MANY at the present time who are only familiar with the glass positives taken by the itinerant photographers of the sea-beach and holiday resorts, have but little conception of the beauty and delicacy of a really good collodion positive. The productions just alluded to are little short of libels on the process. Moreover, a collodion positive, if varnished, is one of the most, if not the most, permanent of all silver pictures. For some few years—1851 to 1855—the practice of the collodion process was practically confined to the production of positive pictures, inasmuch as the making of negatives, or, rather, the printing from them, was claimed by Fox-Talbot as being an infringement of his calotype patent. Hence the advancement of photography, so far as the production of collodion negatives was concerned, was retarded for about four years; or until the famous suit of "Talbot v. Laroche" was tried at the end of 1854, when it was decided that this claim could not be sustained. Up to that period only glass positives, to any extent, were made commercially, and they—when made by first-class photographers—competed very keenly with Daguerreotypes in quality, while, of course, they could be produced at a much cheaper rate. For delicacy and fineness of detail they were but little inferior to Daguerreotypes, and some of them closely resembled them in appearance, while they possessed the advantage that they could be viewed in any light.

### Collodion Positives

It may be as well here to say a few words on the difference between a collodion positive and a collodion negative, for they are both, to an extent, the same. For example, if a collodion negative is looked down upon with something dark beneath, it shows as a positive, though not as a good one, and if a positive is looked through it shows as a negative, though an exceedingly thin one. In a word, a glass positive may well be described as an under-exposed and under-developed negative, so closely are the two allied. The difference between glass positives and ferrotypes is simply that the former are taken on glass plates and afterwards backed with a dark material, and the latter are taken direct on an opaque material—the now well known ferrotype plates. The manipulations with the two are precisely the same whichever is used, and they do not differ materially from those in the production of negatives, but the conditions to be observed differ. In making a negative the object is to get density in the image as well as detail. In a positive it is to obtain detail with great thinness. Also as the blacks are formed by the backing material, whatever that may be, it is imperative that the deepest shadows of the picture must be free from any trace of veiling, or the picture will be lacking in brilliancy.

### Manipulation in Making Positives.

The practical working of the process will now be described. The plates, whether glass or ferrotype, should be cleaned in the same way as for negatives, and the same scrupulous cleanliness must be observed throughout all the manipulations. The collodion for positives may be a little thinner than is desirable for negatives—say a drachm of a mixture of equal parts of ether and alcohol added to each ounce of it. The novice will probably get on best by purchasing collodion specially made for positives—say, such as that supplied by Mawson and Swan. The collodion is best used two or three months after iodising, so that it is highly coloured. If it has to be used soon after iodising a little solution of iodine in alcohol should be added to give

it almost the colour of port wine. The silver bath, too, should not be quite so strong as for negatives, and it may be made a little more acid. A good formula for a positive bath is:—

Nitrate of silver .....	2 ozs.
Distilled water .....	30 ozs.
Nitric acid (pure) .....	4 minims

The bath must be saturated with iodide of silver in the manner described for negatives (see previous articles) and filtered. It is then tested with a trial plate in like manner, and, if found defective, corrected in the same way as then directed.

### A Developer for Positives.

For the developer for negatives the common sulphate of iron (copperas) was recommended, as that conducted to density in the image. But density is to be avoided in the present instance; the pure proto-sulphate of iron should be employed, according to a formula such as:—

Proto-sulphate of iron .....	$\frac{1}{2}$ oz.
Glacial acetic acid .....	1 oz.
Nitric acid .....	10 minims
Water .....	20 ozs.
Alcohol .....	q.s.

The larger the proportion of nitric acid the more metallic-looking will be the image. If the acetic acid be omitted entirely and its place taken by a larger proportion of nitric acid, the picture will partake somewhat of the character of a Daguerreotype, but there may be a lack of half-tone if too much is employed.

Another formula for a developer that yields very white and clear images, even better than the one just given, is as follows; but it is a little more trouble to prepare:—

Proto-sulphate of iron .....	$\frac{1}{2}$ ozs.
Nitrate of baryta .....	1 oz.
Nitric acid .....	2 drachms
Water .....	20 ozs.
Alcohol .....	q.s.

The iron should be dissolved in half the water and the baryta in the other half and the two mixed together. Then the precipitated sulphate of baryta is filtered out and the nitric acid and alcohol added.

### Some Minor Precautions.

The exposure required for positives is not more than half that necessary for negatives, therefore it is really a more rapid process. The developer is applied in the same way as for negatives, but it may be used a little more lavishly, as it is not desirable to have too much silver solution on the plate, since a dense deposit has to be avoided. The development must be carefully watched—looking down on the plate and not through it; as soon as detail appears in the deepest shadows, indeed, almost before that, the plate is quickly washed under the tap. It is then fixed with a solution of cyanide of potassium—about 10 grains to the ounce of water. This may be used by flowing over the plate or in a bath. Hypo is not good for fixing positives, as it does not leave such a white and brilliant image as does the cyanide. The washing after development should be very complete, or blue stains may result from the formation of Prussian blue in the film when the cyanide is applied. After fixing the picture is well washed and dried. The drying may be hastened by heat, if desired, without fear of its being injured. The plate is then varnished with a colourless varnish to prevent the atmosphere from tarnishing the silver.

the most suitable varnish for collodion positives is dammar, as follows:—

Batavian dammar .....	2 ozs.
Benzole (pure) .....	1 pint

Dissolve, allow to settle, and then decant the clear portion, the varnish may be filtered through paper or cotton-wool as the resin is all dissolved. This is applied to the picture, in the same way as the collodion, and it dries in a few minutes. It goes without saying that the film must be thoroughly dry before the varnish is applied, otherwise it will dry bright or transparent. If our picture has been taken on a ferrotype plate it is finished and ready for framing. But if it is on glass it will require backing with black varnish, or a piece of black velvet. If the black varnish, such as 'Black', be used it may be applied with a brush, and a thin coating, which dries quicker than a thick one, will suffice. Our picture is now reversed, as regards right and left, as all ferrotypes must be; but when taken on glass that need not be. All that has to be done, after it is varnished with the black varnish, is to turn it over and put black velvet on the film side; we then have the picture the right way about. Instead of using the dammar varnish, when a non-reversed picture is desired, the black varnish may be applied direct on the film. In this case the picture is seen through the glass, the image then is not so white when seen from the under side of the film as it is when viewed from the upper side, and, moreover, the black varnish has a tendency, when applied direct to the film, to degrade the whites. When a non-reversed picture is desired it is best to varnish it with the dammar varnish and then place it in the frame, or case, with a piece of black or purple velvet underneath. In this way the whites are purer and whiter than if black varnish were applied on the film.

Collodion pictures can be, and sometimes are, whitened by a saturated solution of bichloride of mercury. They were called "alabastine" pictures and were well suited for printing, which used to be done with powder-colours in the same way that Daguerreotypes were coloured.

In the foregoing chapters the collodion process has only been dealt with on the presupposition that the plates are to be used in the wet state, and directly after they are sensitised. There are, however, dry collodion processes, their name is legion. In the olden days almost every photographer had his pet process, in many cases one of his own invention, yet all of them were workable and capable of yielding excellent results. But in all the plates, in the first instance, had to be prepared in the same way as if they were to be exposed in the wet state. They were then treated with afterwards by different substances which acted as preservatives, or the collodion film was kept in such a state that it was easily developed by the developer. Amongst the most favourite dry-collodion processes may be mentioned the Fothergill, the tannin, the gallic, coffee, and morphine. With all the many dry-collodion processes the plates were very much slower than if they were exposed in the wet state, while the after operations were both tedious and troublesome. It is, therefore, not necessary to refer further to dry collodion processes. The same may be said with regard to the collodio-bromide process, which does not come within the scope of these articles, although it is really a collodion process.

Before concluding this series of articles it will be advisable to say something on the failures and defects that may possibly be met with, and their remedies. It must not be expected that a beginner in any, to him, new processes of a character of collodion process will not meet with some little troubles which he at first does not understand, although the preceding writers have aimed at giving instructions which, if carefully followed, would reduce them to a minimum. However, we will

now allude to some of the principal difficulties which may trouble the novice.

*Fogging of the Negative.*—This may arise from several causes. One may be too much actinic light in the dark-room or diffused light in the camera. The remedy for this is obvious. The plate may fog all over directly the developer is poured on and before the image appears. This, provided the developer is made in accord with the formulæ, is due to the bath. If the latter is a new one, the addition of two or three drops of nitric acid to the pint of solution should set matters right. If it does not, the bath should be made neutral, say, with a little carbonate of soda, or sunned for a day or two, then filtered and once more be made slightly acid. Should the negatives on development show only a slight superficial fog on the shadows it is probably due to the collodion, particularly if it is freshly iodised. This kind of fog can generally be cured by the addition to the collodion of some that has been iodised for some months, or by adding to it a little solution of iodine in alcohol, sufficient to give it a strong colour. It is always a good plan to have some old iodised collodion, which has become a very dark colour by keeping, in stock to be used in a case of this sort. Fogging may arise from excessive over-exposure, but that differs from that arising from the bath, inasmuch as, in this case, the image flashes out before the actual fogging sets in. It is needless for us to give the remedy.

*Wavy Marks in the Direction of the Dip.*—Several causes exist. One is that the plate was immersed in the bath too soon after it was coated with the collodion, or maybe it was not moved about while it was in the bath. As soon as the plate is put into the solution it should be moved about, first laterally a few times, and then rapidly removed and replaced several times so as to get rid of the solvents of the collodion as quickly as possible. This trouble is more prone to arise with newly iodised collodion than with old. Another prolific cause of these streaks is removing the plate from the bath and putting it in the slide before the collodion film is free from "greasiness" and the solution does not drain evenly from it. Sometimes fine black lines are seen in the direction of the dip when the negative is developed. These seldom make their appearance except with an old and well-used bath, but they may for a time be usually avoided by keeping the plate moving laterally for the greater part of the time it is in the bath. If that does not mend matters the bath should be discarded until it has been doctored. Sharp lines horizontally across the plate are due to a momentary check in immersing the plate in the bath. The plate must be lowered into the solution without the slightest stop.

*Lack of Density in the Negatives,* as with other troubles, may be due to several causes. One may be that the plate was too long in the bath, if that happen to be a new one, and is not completely saturated with iodide of silver, so that the silver solution has taken away some of the iodide of silver out of the film. Another is that the plate is under-exposed, or the iron development was not continued long enough to get a sufficient deposit of silver on the image upon which the intensifier might act. Another, again, may be that the plate was removed from the silver bath before all the iodide in film was converted into the iodide of silver. Still another cause of thinness of the image may arise by the use, in fixing, of a too strong solution of cyanide of potassium which has reduced the density of the image already obtained. This trouble is never likely to arise when hypo is used as the fixing agent. Thinness of the image may also be due to the plate being kept too long between sensitising and development, the solution on it becoming concentrated and dissolving some of the iodide of silver out of the film—iodide of silver is more soluble in a strong solution of nitrate of silver than in a weak one. Trouble from this cause is more likely to arise in hot weather than cold.

*"Oyster-shell" Markings.*—These are so called because in their

appearance they somewhat resemble the oyster-shell. It is a deposit of metallic silver starting from the bottom of the plate as it was in the camera. When the negative is dry the deposit can usually be wiped off with the finger, but then there is no image, or very little, beneath it. These markings are due to the silver solution, after draining down and becoming contaminated by the dark-slide, ascending the film by capillary attraction, and becoming reduced to the metallic state when the developer is applied. This trouble is another that is more prone to arise in hot weather than cold. The remedy is to drain the plate very closely and to wipe the back of it before putting it into the slide, so that there is little or no solution to drain down; also to put slips of blotting-paper in the corners of the slide or carrier to absorb what little does run down. When the wave-bath is used there is but little risk of oyster-shell markings, as in it the plate can be very completely drained without fear of its drying.

*"Crapiness" in the Film.*—This may be due to two causes. One is an unsuitable pyroxyline in making the collodion; another the use of too weak solvents for it. If any of the commercial collodions be employed this defect is not likely to be met with, unless the collodion which has become thick in use is diluted with too weak ether and alcohol. For thinning collodion ether of .820 and absolute alcohol alone should be employed.

*Mottled Stains Seen when the Negative is Developed.*—These are usually due to the developer not being evenly flowed over the plate. When the bath has been long in use, and become well charged with the solvents of the collodion, the film becomes very repellent of the developer. The remedy in this case is the addition of more alcohol to the developer to ensure its flowing freely.

*Pinholes, Black Spots, and Comets.*—The first named and

their cause are fully dealt with in an earlier chapter to which the reader is referred. Small black spots and comets are mostly due to the dust either in the dark-room or the camera. Both the latter and the slides should always be kept well dusted, and a slightly wet wash-leather is the best duster for the purpose. The comets may possibly also be due to particles in the tap-water used for washing the plates during development. One or two thicknesses of fine flannel should be loosely tied over the tap, which will retain these dust particles.

*Collodion Splitting off the Plate when the Negative is Developed.*—This trouble may be brought about by using too contract collodion, or one that is too newly iodised. But more likely it is due to the glass not being perfectly cleaned before collodion is applied, or possibly there was a very slight amount of moisture on it when it is coated. Roughening the surface of the plates, or with a brush coating the edges of the plates with diluted albumen, will prevent the collodion splitting at the edges.

*The Collodion Film Partially Dissolving when the Negative is Developed.*—This will only occur when very old collodion is used and the spirit in the varnish is exceptionally strong. The plate made unduly hot. A little water added to the developer will usually obviate this. If not, a little diluted albumen flowed over the negative after it is washed will prove a certain remedy.

Other troubles than those enumerated may possibly arise in working the collodion process; but those referred to are the principal ones that are likely to beset the beginner, and will now know how to overcome them.

In conclusion, we would once more emphasise the absolute necessity of care and cleanliness throughout all the operations in working the collodion process, as, without that, complete success cannot be expected.

E. W. FOXALL

## REAGENTS FOR REDUCING BROMIDE PRINTS TONED TO SEPIA BY THE SULPHIDE PROCESS.

[It is obvious from this note, communicated by Mr. Harry E. Smith to the "Photographic Journal," that the general accepted opinion that sulphide toned prints cannot be chemically attacked is unsound. When considered with Mr. Carnegie's paper, to which reference is made, it would seem desirable that more work should be done on this subject.—EDS., "B.J."]

It is generally supposed that bromide prints toned to a sepia colour by the sulphide process are permanent, and, indeed, as regards their susceptibility to atmospheric influences, this seems to have been proved conclusively to be so.

Having accumulated a number of sepia-toned prints that were too dark, and as there was apparently no known method of reducing them, I was led to experiment with a view to finding a satisfactory reducer. As a result of these experiments, I give the following list of reagents that will more or less satisfactorily reduce a sulphide toned print by converting part of the silver sulphide into a haloid compound of silver, which is of course easily removed by an ordinary fixing-bath. Perhaps I may here allay any momentary feeling of alarm in the case of those having sepia bromides that they value by saying that the reagents which I recommend are in most cases very unlikely to be present in the air to any appreciable extent, and in many cases it would be practically impossible for them to be so under ordinary atmospheric conditions.

The reagents that I recommend are the following:—

1. Cupric chloride and sodium chloride in aqueous solution.
2. Cupric bromide in aqueous solution.
3. Cupric chloride in aqueous solution.
4. Chlorine water.

5. Bromine water.

6. Iodine in aqueous solution of potassium iodide.

7. Iodine in aqueous solution.

8. Iodine in alcohol.

9. Solution of potassium permanganate acidified with sulphuric acid.

Some other combination of metallic chlorides also act more or less on the sulphide image:  $\text{CuCl}_2$ ,  $2\text{KCl}$  is an instance of this type of substance which is quite successful in its action, unfortunately some of the double chlorides are decomposed by water.

The above nine reagents are placed roughly in order of merit. The fact that  $\text{CuCl}_2$  and  $\text{NaCl}$  will break up  $\text{Ag}_2\text{S}$ , has been a chemical fact known for some years, of course; but I think that the compound has not been applied to the reduction of sepia bromides, though it seems particularly suitable for this purpose owing to the solubility of both cupric sodium chloride and cuprous sodium chloride. As a satisfactory working mixture I recommend a mixture of equal bulk of 5 per cent. cupric chloride solution and 15 per cent. sodium chloride solution. After reduction has gone far enough, the prints should be placed in a bath of hypo, ordinary strength, with the usual wash after fixation. I prefer to wash for five minutes between reduction and fixing.

fixing, but this is not imperative. The fixing-bath quickly dissolves the silver chloride from the reduced print, and the sepia tones are well preserved; in many cases the tones gain in colour and brilliancy in this way.

The smell of chlorine and bromine water is unfortunately not to their favour; but iodine in water seems to be satisfactory, and there appears to be nothing gained by using a tincture of iodine. Iodine in potassium iodide is the most rapid and effective reducer that I have found in this connection; it will quickly and entirely bleach a sulphided bromide print. Iodine, however, in any case, open to the objection that the iodide of copper formed in the paper masks the action somewhat, so that the true extent of the reduction cannot be judged until the print is placed in the fixing-bath, which, of course, quickly discharges the blue colour. The cupric chloride and sodium chloride soluble-bleached the ordinary black silver image; but I have not found that this method of bleaching presents any particular advantage over other bleachers. To rectify a sepia tone that is too near a black, caused by a faulty sulphide bath or insufficient bleaching, I would not recommend the use of iodine in potassium iodide unless at the same time considerable reduction is required or unless the solution is either used very dilute or for a very short time only, say seconds, for example, for a length of water 100 cc. KI 3 grammes and I 1 gramme, iodine 1 part, potassium iodide 3 parts, water 100 parts.

The cupric mixture is used to improve the sulphided image; the print should be washed afterwards for five minutes in running water, then treated with 5 per cent. nitric acid for about five minutes, and again washed in running water for five minutes. The print may be again sulphided with sodium sulphide or other sulphiding solution. In many cases the tone is changed to a much warmer and richer brown. The nitric acid removes the copper from the print, thus preventing staining when the sulphiding solution is added. The fact that copper is left in the print after treatment with the cupric solution would seem to point to an analogous action to that of cuprous bromide on a black silver image, which was discovered and so accurately investigated by Sir William Abney many years ago.

I have prepared silver sulphide by precipitation with sulphated hydrogen, and find that the action is much slower in the case of a precipitated salt than in a print. I have not been able to decide what the action is that takes place in the case of the precipitated salt, and I do not think that the reaction in the print is so simple as

The statements that I have been able to look up regarding the action of the cupric mixture on silver sulphide seem to be rather contradictory. In Fremy's "Encyclopédie" 27/29, page 29, we find the statement that sodium chloride reduces silver sulphide, giving silver chloride, sulphate of soda, and sulphurous acid. The fact that the shadows of a print are perfectly cleared up by fixing with hypo seems to show that no sulphur is deposited on the film. The fact that none of the reagents I have mentioned will bleach the sulphided image completely (except iodine in potassium iodide), but leave an apparently unalterable

brownish red image, would seem to show that the sulphided image consists of at least two different substances, though doubtless the greater part of it consists of silver sulphide.

After acting on the sulphided image as far as possible with the cupric mixture, and mixing, the fact that a solution of potassium permanganate acidified with sulphuric acid, instead of dissolving the light image with separation of silver, dissolves it away entirely (Von der Pfordten "Ber." 20, 1458/1474), would seem to point to a difference in constitution of the red image from silver sub-sulphide  $\text{Ag}_2\text{S}$ . I fear, however, that no definite conclusion can be drawn from this or from the fact that the same light brownish-red image is apparently insoluble in warm dilute nitric acid (of course, the print was treated with formalin before subjecting it to the action of warm dilute nitric acid).

The chemical action on a sulphided print appears to differ greatly from the action on silver sulphide prepared in the laboratory, and I think that I may cite as a case in point that citric acid in aqueous solution, with addition of potassium nitrate, has apparently no effect on a sepia print, even when the print is treated with formalin and subjected to the action of this mixture at 43 deg. C. Yet this mixture is mentioned (by Belton C. N. 37-98) as a solvent of silver sulphide, on heating, it is true; but, still, bearing in mind the much finer state of division of the sulphide compound in a sepia print, one would expect to find some effect. Again, F. W. Hinrichsen and Tosio Watanabe, in the "Abstracts of the Chemical Society," 1906, page 85, state that the decomposition of silver sulphide by a solution of sodium chloride can only take place to a very limited extent owing to the very slight solubility of silver chloride. Perhaps, however, I should not quote this as tending to show a difference between the prepared silver sulphide and the sulphide image, as, of course, the solution that I find to act so quickly in decomposing the sulphide image contains also cupric chloride. I have not tried the effect of potassium cyanide on a sepia print as, although it is stated to dissolve silver sulphide, few would care to use so poisonous a substance when, as I have shown, there are several other satisfactory and harmless reducers of the sepia image.

I have, of course, avoided trending on the sphere of investigation that Mr. Carnegie has taken up ("B.J." Almanac, 1907), but I think it will be admitted that the experiments that I have made tend to confirm Mr. Carnegie's theory as to the probable constitution of the sulphide image, at all events in so far as they seem to show that the light red image (not affected by the reducing agents I have mentioned) does not consist of silver sub-sulphide ( $\text{Ag}_2\text{S}$ ).

Finally, perhaps, I may recommend that for reduction only of a sepia-toned bromide print, the easiest method seems to be to keep the iodine in potassium iodide solution, of the strength above given, as a stock solution. If it is diluted before use up to ten times its bulk with water, reduction, not being so rapid, is easier to follow, and as a set-off against the momentary trouble of the blue stain we have the fact that there is no question in this case of copper being left in the print, which seems to be of greater importance.

HARRY E. SMITH.

PLAYERTYPE.—In reference to the paragraph last week on this subject, Mr. S. C. Puddy writes:—The process described in the "Lancet" mentioned is a method of producing positives direct by phosphorescent printing, and is quite different to that used for photographic prints, and is not what is usually known as "Playertype," though it is also the invention of Mr. Player. The phosphorescent printing mentioned, whilst it is a very interesting and curious process, I should think, of practical value, as when some examples of it were shown at a meeting of the R.P.S. in 1904, it was remarked that the prints showed an appearance of the lines having spread,

and that the image did not appear to be sharp and clear. ("Photographic Journal," November, 1904, page 303.) The "Playertype" process, by which the prints I sent you were made, will render the lines quite sharp and clear. It was invented by Mr. Player in 1896, and was first mentioned in the "Amateur Photographer," November 13, 1896, page 398, where a description of it is given, though mention is omitted of the yellow screen which is necessary, and also one or two other essential points. A printing frame is mentioned in the article referred to, but this is not necessary, and when copying prints from a book it is not convenient.

## NIGHT PHOTOGRAPHY.

[The fascinating subject of night photography has probably never been treated in a paper as exhaustive as that recently delivered before the Edinburgh Photographic Society by Mr. Robert Dykes, assistant photographer. Mr. Dykes has pursued his hobby in Edinburgh, Paris, and London, and one cannot recommend a better series of hints and precautions necessary in this branch of work than those which he has set forth.—Eds. "B.J."]

No special apparatus is required—night photographs may be taken with the diminutive five-shilling "Brownie" or the large 15 x 12 field camera. Any old box with a lens in it that will take fairly sharp pictures by day will also take them by night. Of course, the man with the stand camera has the advantage, he feels more sure of his work, and knows what he is doing, at least what his camera is capable of doing for him. A great deal is to be said for a fixed focus camera, as it saves considerable trouble in focussing, but a full-sized finder is necessary, otherwise an undesirable light on the left or right front that should be cut out will, in all probability, be left in. In stand cameras, the best form is a square bellows with an extensive rising front; if a conical bellows be used, see that it has loops for looping up to prevent cutting off any light. If the lens is carried on a panel, which is decidedly preferable as it enables the front to be removed, if necessary, for stopping down after focussing, when one cannot very well see the F. numbers, this panel should be one easily removed, but quite firm when put in place again. It is much easier to remove a panel than to unscrew a lens. A fine ground glass screen is an absolute necessity in night photography, and focussing glass cannot be dispensed with. Grease spots are, however, of very little use for focussing, as one never exactly knows where the glass is likely to be applied on the screen. However, this applies to focussing stand cameras, and after all what one really requires in night work, providing one has a camera and lens at all, is a rigid, steady tripod, and the camera perfectly levelled, and last, but not least, a good stock of patience and confidence in oneself. You need it, especially in crowded places, where the plaintive wail of "Please to take ma photv" or other choice remarks are hurled at you. If there is a strong wind blowing it is impossible to do anything, and it is better, if one cannot get a sheltered position, to abandon the attempt. I have walked six or seven miles to get a certain view, and then had to give it up owing to wind. So that even on the quietest of nights the tripod must be well set and free from vibrations. As to levelling, the levels ought to be placed where one can see them easily, no matter at what height they may be, and for that purpose there is nothing to beat Taylor, Taylor and Hobson's single tube levels with the small side slit. I use one at the top of my swing-back for horizontal levelling, and one at the bottom, placed at the side, for vertical levelling. No matter how far above my head they may be, I can see the bubble cross the slit. To do this you must have a light. I myself use wax vestas, a piece of candle, or, if cycling, my cycle lamp, but a very handy thing to have is a small electric torch. It is essential that care should be taken in levelling the camera, as some frightfully distorted, intoxicated looking lamp-posts or buildings will be the result, and you will certainly be told if you show such productions that you must have been out that night.

A lens hood is useful to keep out too closely situated lights on the left or right lens front, one that, although it does not come into the photograph, is likely to cause "flare" or "ghost" images through internal reflection in the lens. I use a small cardboard box about four inches deep by six inches wide with a hole in the bottom sufficiently large to allow of it being slipped over the lens, top upwards; this makes a very efficient hood.

When working in wet weather a waterproof cover is necessary for the camera, also care must be taken to keep rain off the front of the lens. The lens may be wiped with a soft rag kept for the purpose even during the exposure, providing precautions are taken not to move the camera in any way. I have emphasised the importance of the camera being perfectly steady during exposure, therefore it is hardly necessary for me to warn photographers to avoid bridges where there is any fear of vibration through traffic.

### Which Lens to Use.

As every photographer knows, the better the lens the better the photograph, but the cheapest of lenses nowadays give remarkably

fine pictures, and except for the fact that to obtain a sharp negative it is necessary to stop down and so increase the exposure, any will suffice. The man with the rapid lens working at F.4 or abouts can take very short exposures. A great deal was heard of a new lens invented by Dr. Grün some few years ago, but which became of it now I am not aware. It was said to work at an aperture of F.2, enabling exposures as rapid as one-fourth of a second to be made upon open, well-lighted views. Quick exposures also tried with success, I believe, in theatres during a performance under ordinary conditions of lighting.

Whatever may be the lens used, the aperture best suitable for work is in my opinion F.11, and in some cases even F.16, so with a lens having a full aperture of about F.7 we can increase depth, make more sure of our focus, and the sharpness of our lights by putting in a couple of stops. The sharper the light the less chance of halation. All exposures should be made with the shutter as it may be necessary to put it on and off during the exposure a shutter is not easily opened or shut without jarring the camera. Care should be taken to see that the lens is firmly fixed and unlikely to fall out of the camera front. Many of these remarks sound absurd, but even to the most cautious worker the unexpected may happen.

Coming now to the question of plates, any plate may be used, no matter how quick or how slow, only, as we do not care to wait about all night over an exposure, the quicker the plate the better.

### Ordinary or Orthochromatic.

About one of the best all-round plates on the market is the I "Monarch." It is clean, rapid, and if purchased already backed quite ready for use. Some plates are very poorly backed when by the makers, it being put on in a streaky fashion, and such backing is desirable. I find Mawson's "Antalo" does very well and if the subject I intend photographing has many high lights I give my plate a coat on the top of the maker's backing. It is absolutely essential that they be backed, unless one is using double-coated plates such as the "Seed." I have used these latter frequently unbacked, and obtained splendid results. A good double-coated plate is certainly the thing to use if it is intended to make lantern slides of the views taken, as there is far less halation than in single-coated plates; the high lights stand out clear and crisp, and free from circles, flare, and radiating rays, the latter due to structural backing. Avoid putting on backing in a streaky fashion, or the result may be disastrous. The marks develop up very frequently, causing peculiar Aurora Borealis effects up the plate.

Snapshots isochromatic plates are suitable in some cases, but I rule I avoid them for night work, although I would not be without them for daylight exposures on any account. There is far too great a risk of light and chemical fog in this development, which is necessarily prolonged, not to mention the fact that they have always proved themselves much slower in my hands than ordinary rapid plates.

Films may be used and need no backing, as owing to their extreme thinness and the fact that they have a paper backing they are very free from halation.

No matter how well backed a plate may be, halation is entirely prevented, and except where enlarging is resorted to a little is necessary for pictorial purposes.

Before attempting to give some idea of exposure and the method of development, I might with advantage offer a little advice as to prospecting for likely views, and some of the things to avoid.

### Hunting for Subjects.

Prospecting should most certainly be done without a camera, the man who wanders about the streets of a great city by night with half a hundredweight of photographic apparatus will soon find that the camera and himself were elsewhere than where they are

ice subjects should be noted at all times either by day or night, visited again by night if they were first observed in daylight, or which it is a comparatively simple matter to go straight to selected spot and make an exposure.

It may be possible to do more than one view in a night. I have managed to pull off four between the hours of eight and ten o'clock, but it is far better to do one good plate than take a dozen indifferent ones, because the exposure is not the most onerous part of the work by any means. The worst part has to come in the development.

In choosing a point of view to photograph from certain little things should not be overlooked. In the first place the nearest and brightest light, whether it is objectionable, and if so, how best to avoid it. The best time of night for taking a view must be considered: if too late at night a great amount of the light is required to build up the picture may be off owing to shops shutting.

Then if too early in the evening there may be a great many bright lights, or what is worse—a cab rank, and cab ranks are a nuisance at night from a photographic point of view. Or perhaps one may be photographing in a park when it is just about dark, and the camera must perforce close also and you clear out. All means avoid motor cars, they occasionally do go, and when they do—well, they are a little faster than the plate you may be using; but apart from the fact that if standing in the middle of a road you are liable to be removed suddenly, it is the powerful kerosene lamps they carry that one must avoid and the lens capped instantly. Bicycles or any forms of vehicular traffic carrying lights led be carefully kept out of the lens no matter how rapidly they may be moving, or the plate will be crossed by innumerable white lines that on printing will look like scratches, clothes lines, or graph wires. On no account obstruct the traffic or a long coat slung about by a helmet may loom up out of the darkness and order to “move hon.”

During preparation for your exposure do not converse with bystanders or you may expose the wrong plate—this is easily done in the darkness; or perchance you may do something more absurd, as the writer did once, enter into conversation with a gentleman thinking that the exposure was going on, and the cap never removed from the lens at all.

Keep loiterers out of the immediate vicinity of the camera front, it is impossible to include any form of life in a night photograph unless the person or persons remain in the same place during the whole of the exposure. This may be arranged for in some scenes by getting friends to stand for short exposures of between five and ten minutes, provided they are able to recline against something solidly. People and other objects moving even slowly have no effect upon the plate, but keep them moving.

You may be pestered to “please take my photo,” or by a noisy crowd of a newsboy who wants you to “snatch my dial, guv’nor,” before you can kick it, disappears. If your attention is taken from your camera for a moment an individual may be kind enough to step over it; this happened to me not long since and the person who didn’t get a squint; if he had, there might have been some excuse for his trying to go where he was looking. In dealing with the public one must not be too reserved nor yet too free; politeness and common sense go well together with a little spicy language thrown in occasionally. If you don’t respond when addressed by certain persons they will become emboldened, take you for a foreigner, and begin speaking a language decidedly strong, which you must take care to give up as good a grace as possible if you wish to hold your ground. I have had a mob of half and wholly intoxicated individuals around me at night, and it was a draw as regards conversational powers, although I was a bit dry after it.

Don’t attempt photographing in low-class quarters of large cities without having one or two friends to accompany you. It is in some of the slum districts, generally speaking, that one finds good pictures, but a bull-dog or a couple of friends are indispensable. You have a revolver in your pocket, but what is the good of it if you are taken unawares with your head under the focussing cap? The suburbs and certain parts of the city of Paris are very dangerous, especially around Montmartre, and some of the streets near the Ile de la Cité. London in the East End and Glasgow in the vicinity of the docks, Edinburgh, and all other large towns, have also their haunts of crime and vice. So far I have

always worked alone, and although at times I have been in queer corners, have never yet been cornered.

### A Table of Exposures.

I have prepared a table of exposures which may be of some assistance, providing one’s own judgment is used as to increasing or decreasing the exposure by five minutes according to the quality of light. The table is only approximate, and a little latitude on the side of over-exposure can be easily remedied in the dark-room, as it is certainly better to have something on a plate than nothing at all through under-exposure. If the sky be particularly dark there is not much risk of over-exposure, it is when illuminated by a full moon or on summer nights when distinctly blue that one runs the risk. There is an old saying with regard to daylight work—viz., “expose for the shadows and let the high-lights take care of themselves”; well, this is equally applicable to night work. Get all the details possible out of the shadows, and the worst that can happen is reversal of the centre portions of high-lights such as arc lamps; it is comparatively simple to put this right with a brush.

TABLE OF APPROXIMATE EXPOSURES FOR NIGHT WORK.

Subject.	Weather.	Month.	Time.	Stop.	Plate.	Exposure.
Open street scenes, squares, monuments, views, illuminations, &c., well lighted with either electric or incandescent gas.	Clear, cloudless with or without frost, after a heavy fall of snow, with a full or half moon, or a shower or rain with wet pavements, &c.	From Sept. to Feb.†	8.30 P.M. to 3 A.M.‡	F. 11 §	“Seed”	15 minutes
					Ilford Monarch	20 “
					Imperial Special Rapid	30 “
Country scene, or any view, or no artificial lighting.	Only possible under above weather conditions.	Ditto.	Ditto.	Ditto.	“Seed”	30 minutes
					Ilford Monarch	40 “
					Imperial Special Rapid	50 to 1 hour
Close views in small squares, or in dark corners, or in dark squares not too well lighted. Principal objects in foreground.	Ditto.*	Ditto.	Ditto.	Ditto.	“Seed”	20 minutes
					Ilford Monarch	30 “
					Imperial Special Rapid	40 “

\* Any other conditions than these, such as no moon, very dark and overcast, cloudy, no rain or wet reflections, no snow, add ten minutes.

† During summer months five minutes should be deducted when the sky is cloudless.

‡ During summer months 11 p.m. to 2 a.m.

§ Stop value the same as for daylight work.

With a “Spectrum” plate and a lens working at F. 8, an exposure of one minute, or even in some cases of ten seconds, is possible. I have obtained a negative with an Ilford Monarch, Cooke lens F. 6.5 and an exposure of fifteen seconds. The above exposures are very full, and it may be necessary sometimes to shorten them, but it is advisable not to do so if possible.

### Development.

Having been out in the dark we will now go into the dark-room, and here commences the real work of night photography. In the first place cleanliness has to be strictly observed, clean dishes, clean hands, clear solutions free from sediment, and a perfectly safe light. Whatever developer we may use, and we all have our favourites, it must be diluted down very considerably, quick developers such as Rodinal more so than slow ones such as pyro soda, for our plate has to be coaxed up slowly, not driven or forced. On no account should a plate be developed in less than twenty minutes or over forty minutes; generally speaking it may be finished in half an hour. One of the main reasons for failure by many who attempt night photography is that they invariably treat the plate much the same way as they would a daylight exposure, and as a consequence up flash all the high-lights black and dense, and the shadows—well,

there is nothing else but shadow when the plate is fixed, with a lot of black circles indicative of light.

To develop the plate, the gelatine surface of which should on no account be fingered, it is placed in a perfectly clean dish film up and flooded with the diluted developer; it is then covered up, and rocked well to free of any likely air bubbles. After having been in the developer for a few moments the plate is removed, and either placed into a large dish with cold water or put film up under a running tap, and held there whilst the backing is removed with a tuft of cotton wool. The light should be turned down as much as possible without inconvenience to prevent any chance of fog. Unequal development would take place due to draining off of the developer if we were to remove the backing without keeping the film flooded with water. After the backing has been removed, the plate and dish should be well rinsed and then flooded with fresh developer sufficient to cover the plate about one inch deep. It is then covered up and may be safely left without continuous rocking for ten minutes, a slight rock being given at odd intervals.

On no account should the plate be examined by transmitted light; always look at it by reflected light as it lies in the dish; and before renewing the developer, which should be done every ten minutes, thoroughly rinse off the old stuff. To one not accustomed to the appearance of a night negative, it may be somewhat disconcerting to find next to nothing on the plate after twenty minutes' development, but it must be remembered that our view is a night one, therefore the shadows will largely predominate, and shadows are in a negative almost clear glass. Do not examine the plate too much during development; I never look at mine until well over ten minutes. You are perfectly safe to leave it; your developer is weak and cannot do any harm. When to stop development is a question most serious, a question oft asked but not so easily answered, at least in daylight work. However, I think that one may safely say that a plate is fully developed when the clear margin around the edge due to the rebate of the carrier begins to get discoloured or smoky; this is a sign that the developer has done its work, and that the unaffected silver salts are being attacked. The blackness of the high-lights should also be taken into consideration; they must be pretty strong, yet not too strong, or they will print out chalky. Having given half an hour or more for the development of a plate that we feel has been pretty correctly exposed, we are quite safe in giving it a rinse in a little stronger developer for a moment, rinsing in water for a minute or so, and placing in the fixing bath. This should be pretty strong, more so, perhaps, than that used for daylight negatives, as there is considerably more silver to remove. I have no special strength—speaking photographically—and pop them into bath made up in a very rough and ready and not too economical way. Thorough fixation is essential, and on no account should the plate be examined by ordinary light until fixation is complete. I never allow less than fifteen to twenty minutes for this operation, and if the plates are double-coated, not less than thirty to forty minutes.

As regards developers, I prefer pyro soda made up according to the "Imperial" formula, which I need not give here; suffice to say that I use about four drachms of the pyro to five drachms of the alkali in about sixteen ounces of water. This is only approximate: I sometimes use it a little weaker or a little stronger. To finish off a plate, I rinse it in one ounce of the normal developer (equal parts of pyro and alkali) in eight ounces of water. This must not be allowed to act on the plate longer than one minute, it is simply used to strengthen up the detail. On no account use bromide in development, unless it be with a camel-hair pencil to retard a too obtrusive high-light.

In using quick developers such as rodinal, dilution must be carried to the extreme, say, perhaps one drachm in twenty ounces of water. Too much pyro soda developer in a diluted state should not be made up at once, as in this condition it is rapidly oxidised, and stains instead of developing the negative. For this reason a plate should certainly not be left longer than ten minutes without changing the solution.

Having fixed, the next proceeding is washing. This ought to be well done in perfectly clean running water, so that on removal from the washing tank there are no specks of grit or other particles adhering to the emulsion.

Precaution must be taken in the drying to ensure a perfect clean negative: finger marks, bits of dust, scratches, etc., all appear only too plainly when the plate is dry if care has not been taken. There is so much clear gelatine present that dust and marks of description are far more serious on a "night-scape" than they would be on a daylight production, particularly if they are required for lantern plate purposes. Stains due to the water trickling down the plate when set up to dry may be prevented by mopping up the superfluous moisture with a very soft piece of rag, free from fluff, such as an old handkerchief.

#### After Processes.

Intensification can only be applied locally to skies. I would strongly advise that a negative that through under-exposure somewhat thin should be thrown away, if it is at all possible to obtain another. I have never yet been able to improve a "night-scape" by intensification except, perhaps, locally, for strengthening traces of cloud in a sky.

Reduction may be attempted with success, but care has to be taken that it is not carried too far. Local reduction is very necessary sometimes when an area shows up too strong in a view. The mechanical Globe Metal Polish reducer is very handy in such cases if carefully used with a stout artist's stump. It is much more preferable to take a view over again if possible than attempt either intensification or reduction.

As to the preservation of the negative, it should be carefully varnished, the plate being well flooded and then thoroughly drained before setting up to dry, for little rills of varnish will print up distinctly. Thin negatives of this description ought to be varnished; they are valuable at all, although I do not varnish my own, and the consequence have lost a goodly number of them through print stains, etc.

Before concluding, some mention may be made of the most suitable methods of printing night views. The best effects are obtained by printing in black or blue carbon—browns, reds, and other colours being, of course, not suitable. Platinum prints stand first and foremost, followed by black or blue carbon, double or single transfer process, according to necessity. Finally, we have S.C.P. for contact work, and bromide paper for either contact or enlarging. I do not enter into details concerning the methods of working the various processes as they are already very well known. There is only one thing I might mention, and that is to ensure thorough fixation, but at the same time not to leave prints too long in fixing bath, or the shadows will lose their rich blackness so necessary for contrasty effects in night views and become grey.

Toning is of no use, but a yellow colour may be imparted to high-lights by immersing the washed print in a solution of potassium permanganate about 2 per cent. in strength. This must be carefully done, for if too much permanganate be used, the print will, after a week or so, turn purple and go off colour. I had the misfortune to exhibit a print treated in this manner, and it had been on exhibition three days before it went purple in the face, presumably with shame.

In mounting and framing every one must suit their own taste, I have found by experience that dead black borders and frames for night pictures off to the best advantage, the margin between print and paper to vary according to the nature of the subject. Very frequently it may be better to frame close up without a margin at all.

In conclusion, whatever may be the nature of the subject photographed at night, keep a note of exposure, weather conditions, etc. It is impossible to remember every little detail, and carefully made notes will be of the greatest assistance in preparing a table of approximate exposures for future work.

ROBERT DYKE

LUMIERE "AUTOCHROME" PLATES.—One of the first specimens of colour photography on the Lumière new "Autochrome" plates is to be seen in the Kelvin'side Art Galleries at Glasgow. The example

is a portrait of Madame Merriot, wife of the Mayor of Lyon, and is lent by Mrs. Bilisland, wife of the Lord Provost of Glasgow.

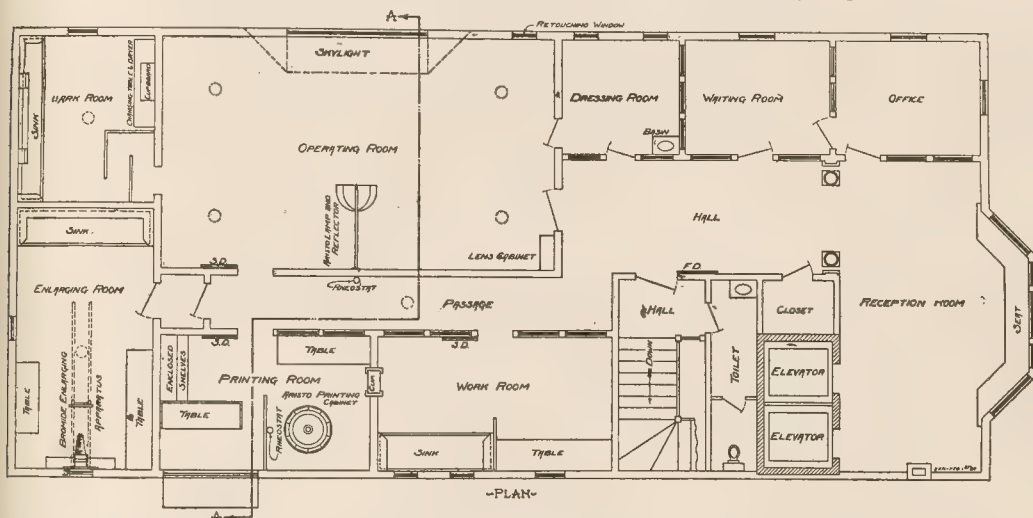

# THE EASTMAN STUDIO AT ROCHESTER, U.S.A.

An interesting account of a model set of premises installed by the Eastman Kodak Co. into their Rochester offices, is given by Mr. F. andas Todd in the current issue of the "Photo-Beacon," from which our plan of the premises is taken.—Ems., "B.J."]

Mr. J. B. GUTHRIE, who is largely responsible for the designing of the studio, would be the very last man to call it a model in the usual acceptance of the word. He simply says that he was permitted to use the amount of space that is ordinarily furnished by the average photographer, which in this case was 40 feet by 90, and it was his business to utilise that space to the best advantage for every phase of photography that could come within the routine of the average city photographer.

Mr. Guthrie was for many years a demonstrator on the road and at his elbow a number of men of similar experience. All of these

trated this. I found Mr. Guthrie rather perturbed about the appliances and accessories for the operating room. He really could not figure out where he was at, when he considered certain experiences. At the outset he had placed in this room only such things as were essential, being of opinion that he would get other accessories as experience showed them to be necessary. The first demonstrator to pay the studio a visit was invited to make a few samples of different kinds of lighting, but before he could get down to business he demanded certain reflectors and screens, which were at once supplied. The second demonstrator to try his paces felt he could not use the

men have called upon thousands of photographers in all parts of the country, and as a consequence have gathered together a great many ideas, and they endeavoured to group as many conveniences as possible into the least possible amount of space. I was informed that as a matter of fact, the arrangements took a very long time to put together. Sometimes the construction of a particular portion

of the premises recommended by number one, and so he was supplied with what he wanted. The third demonstrator was built like the other two in this respect, that he was accustomed to certain accessories, and so he was supplied according to his ideas. The same sitter was used in every instance, first-class negatives were got every time, but the operating-room was fast being filled up with a whole lot of things

of the workrooms would be considered as being practically complete, when some demonstrator would come in from his travels and tell of a clever idea he saw in a certain studio, and at once it would be incorporated, even if a very considerable amount of work had to be torn to pieces for that end.

I need scarcely say the studio is not used for regular work. It is only a suggestion, a very expensive one at that, which ought to be used by every photographer who wants ideas in designing, constructing and decorating his place of business, for it is certainly a thing of beauty and beauty. It will be directly of great benefit to photographers, and I fancy much more so indirectly, because it is a meeting-point where all kinds of ideas are thrashed out. Let me illus-

trate which were of use to the man who had procured them, and to no one else. Mr. Guthrie began to wonder where he was at and what he was going to do with all the appliances that were accumulating on his hands. While in this frame of mind he received a visit from a very famous photographer who very kindly responded to the proposition that he make a few sittings. He was informed that if the accessories did not quite suit him he had merely to say the word and others would be provided. Mr. Photographer was of opinion that there was enough, in fact he would take it as a favour if every

one of the reflectors and shade screens were piled in a corner out of his way. Then he proceeded to make a series of very fine negatives without the aid of the accessories that others had deemed so essential, so the following day every one of them was relegated to the storage, and the photograph reproduced indicates that they still remain there.

In the detail work most interest will centre round the dark-room, enlarging-room, printing-room, and workroom.

The dark-room has inside dimensions of 12 by 14 feet. It is entered by a winding passage-way which faces the developing sink. The latter is a marvel of compactness. Two men can easily work at it and there are water taps, fixing and washing-boxes for each. When the day's work is done there is no excuse for a single article lying on the benches, as there is a place for everything. Even the graduates are hung downward so that they will drip into the sink and be always clean and ready for use. Trays are stored in the racks underneath the bench and any drip from them is caught into a trough. The arrangements for various coloured lights are self-evident, but I would point out that the electric connections are so inter-locked that white light cannot be turned on before the ruby light is turned off.

The opposite side of the room is principally used for drying and loading plates into the holders. Underneath the loading-bench is a

chamber protected by a lattice door, and in this is placed the drying rack with the plates, which are rapidly dried by an electric fan.

The problem in the enlarging and velox room was to make the most use of the available space and keep as much off the floor as possible. The easel for the enlarging camera, it will be observed from the plans, is swung from the ceiling, where it travels by means of rollers on a track and can be clamped securely in any position. The enlarging camera is placed in front of a window, but since daylight is not always reliable, a mercury vapour-lamp is convenient, and can be swung very readily into position. Underneath the tables in this room are a series of drawers in which are placed the various sizes of different brands of paper.

The printing-room plans and that of the workroom almost explain themselves, it always being understood that underneath each table in the printing-room are drawers in which the paper is stored, and underneath the table in the workroom is a convenient supply of mounts. Special attention should be drawn to the cupboard between the printing-room and the workroom, because this compartment has a door on each side, and into it are placed the prints as they come from the frames, which are at once available for toning if on silver, or for development if on platinum.

## OBSERVATIONS ON THE LATENT IMAGE.

[The following paper, read before the Société Française de Photographie, further discusses certain observations of the author, Dr. H. Demole, which were published in our issue of May 10, p. 346.—Eds. "B.J."]

THREE facts have been known for a long time:—

1. A photographic plate, treated with bichromate of potassium for some minutes, acquires the property, after washing and drying in the dark, of giving a negative, when developed in white light, after exposure behind a negative.<sup>1</sup> 2. The prolonged action of light alters the latent image and two reversals are obtained. 3. When the sensitive film is acted upon by light in the presence of oxidisers, the reversal of the image is facilitated.<sup>2</sup>

I proposed to study the action of feeble oxidisers on the latent image, not to destroy it, as happens if it is treated with an energetic oxidiser,<sup>3</sup> but to find a new combination from which one might deduct its constitution.

The oxidisers which gave me the best results were the bichromate, permanganate, and ferricyanide of potassium. I rejected the first because it affects the gelatine, a phenomenon which might mask or nullify the reaction which I wanted to obtain; the second appeared to me to be inadvisable, because of its staining the gelatine, and finally a 1 per cent. solution of potassium ferricyanide was used.

It is possible to use a much more dilute solution, 1:500 or 1:1000, but the time of oxidation is long, and the stronger solution is more convenient when several plates have to be oxidised.

When a plate is exposed in a printing frame or camera, immersed for about four minutes in a 1 per cent. solution of ferricyanide, and then developed<sup>4</sup> after rinsing, a curious phenomenon will be observed, that is, that the development is very slow. If to make it easier the exposure is increased and great over-exposure given, another remarkable fact is noticed, the appearance of the image is not accelerated, and, moreover, there is not the slightest trace of over-exposure.

One may thus expose a Lumière blue-label or Jougla red-label plate in a printing frame for several minutes behind a negative, oxidise for a certain time, and then develop without obtaining a positive, notwithstanding the exposure has been considerably above normal.

If the plate is exposed in the camera, either on a landscape or in copying an original, the oxidation preceding development serves apparently to regulate the time of exposure, and over-exposure does not produce the customary effects, assuming that the time of oxidation has been adjusted to the exposure. I hope to be able to indicate the ratio which ought to exist between the times necessary for the two operations. My experiments were not undertaken with the idea

of creating a new process, but only to clear up one of the most difficult problems of photography.

With development papers<sup>5</sup> the ferricyanide acts as with plates. enlarging a negative, the normal exposure for which was five seconds an exposure of 300 seconds could be given, and the paper then oxidised and developed,<sup>6</sup> without showing the slightest trace of over-exposure.

If in lieu of developing the plate or paper and oxidising in white light, it is exposed to the white light of a candle, a still more remarkable phenomenon is observed; the development, without being accelerated, gives a reversed result. Under the action of these two factors, oxidation after exposure, white light, and development, latent image is reversed, and a "contretype" is obtained.

This action is limited by the duration of exposure. If, for example, a negative requires one second to give a good positive in a printing frame in the ordinary way, it will give a negative if oxidation and development are effected by white light. The time of exposure may be increased to 140 seconds, and a negative always obtained. At 150 seconds the image is always negative but less clear. It is the same for 160 and 170 seconds, but at 180 seconds a positive results; then, after a very short time, it turns into a negative. Nevertheless, this negative appears to be superimposed on a positive and if the latter is feeble the whole by transmitted light appears a negative.

With 200 seconds' exposure a positive is first obtained and then negative. With seven minutes' exposure the image appears as a positive and does not alter, but the clear parts are, however, altered. Finally, with 14 minutes, and probably before, the positive is so time indestructible, if the duration of development does not exceed one minute, and thus by means of two reversals the problem of development in white light, which has been so much sought for, is elucidated.<sup>7</sup>

It only remains to find an explanation of the facts which I have recorded, and which would seem to have a probable origin in the known as solarisation.

One may suppose primarily that the ferricyanide acts on the silver bromide in the same way as do numerous bodies with which the substance unites to form combinations, which are not easily reduced by developers. It is easy to prove that this is not the case. An exposed plate, immersed for some minutes in a 10 per cent. solution

<sup>1</sup> "Phot. News," 1880, p. 304.

<sup>2</sup> "Phot. Journ.," xxvii., p. 201, 451.

<sup>3</sup> Eder's Handbook. French Ed. 1883, p. 69.

<sup>4</sup> After many trials the following developer was adopted:—Potassium bromide, 8 gms.; sodium sulphite (anhydrous), 140 gms.; hydroquinone, 34 gms.; caustic potash, 50 gms.; water to 1,000 ccs. For use dilute 1:5.

<sup>5</sup> A rapid bromide paper was used, but it seems probable that other papers would give like results by slightly varying the conditions.

<sup>6</sup> The formula used was:—Metol, 3 gms.; hydroquinone, 5 gms.; sodium sulphite (anhydrous), 45 gms.; sodium carbonate, 45 gms.; potassium carbonate, 15 gms.; water to 1,000 ccs. For use mix 20 ccs. with 60 ccs. water and 20 ccs. of 1 p.c. potassium bromide.

<sup>7</sup> To reverse the image on paper it is advisable to add to the solution of ferricyanide 5 p.c. of glacial acetic acid.

potassium bromide, then rinsed and developed, is retarded in proportion to the action of the bromide on the developer, and one can prolong the exposure without fear of fog in development. But if such a plate is developed in white light it will not only fog but the image will not be reversed.

The hypothesis which naturally suggests itself as the least complicated to explain the singular reaction described, is based on the chemical nature of the latent image. It has been supposed for a long time that the light acting on the silver bromide in a state of extremely fine division as in the gelatine film, decomposes it with the formation of silver sub-bromide,  $\text{Ag}_2\text{Br}$ , the bromide given off being taken up by the gelatine.

The sub-bromide of silver, a substance which is chemically very unstable, appears apt to be reduced by the developer, and thus the latent image produces by development the visible image. It does not appear unreasonable to suppose that the latent image, thanks to the instability of the molecules, may be prone to consolidate, owing to oxidation.

Calling, say, the substance resulting from this oxidation oxybromide of silver,  $\text{Ag O Br}$ , it would be formed according to the  $4\text{Ag}_2\text{Br} + 4\text{H}_2\text{O} + 3\text{O}_2 = 4\text{AgOBr} + 4\text{AgOH} + 2\text{H}_2\text{O}$ . This oxybromide of silver, which, however, is not known, would be fairly resistant to the action of alkaline developers, even in the presence of white light. Then the silver bromide which surrounds

it and which, in an exposed plate, corresponds to the parts not affected by light, in the presence of a developer, and white light would undergo ordinary reduction, and the image would be reversed.

The mechanism of this reaction recalls very much that of a bichromated plate, which, when exposed to light and developed, gives a "contretypé." In the two cases the latent image is rendered stable, and thus permits the reduction of the surrounding silver bromide.

But the hypothesis, which assumes the formation of an oxybromide,  $\text{Ag O Br}$ , suffers from considerable difficulties, the first of which is that a molecule containing one Br and one O, should be very unstable.

One would be probably very much nearer the truth in supposing with Carey Lea that the latent image is the result of a combination between the silver sub-bromide and bromide. This easily reducible compound would be equally accessible to oxidation, and would give an oxide more complicated but more stable than  $\text{Ag O Br}$ . This substance would resist reduction for a long time, a fact which would explain the reversal of the latent image and the regulation of the time of exposure.

There only remains to explain the second reversal, which is so easily produced by development, if the plate has been oxidised previously to development. The experiments are being continued.

E. DEMOLÉ.

### ON THE LATENT IMAGE.

[A Paper in the "Zeitschrift für Wissenschaftlich Photographie und Photochemie."]

continuation of the experiments carried out in conjunction with Professor Schaum<sup>1</sup> on the nature of the latent image in silver bromide emulsions, it appeared essential to determine what part the gas, which surrounds the emulsion during the exposure, plays in the formation of the latent image. The particular point was the much discussed point of the action of oxygen.

Abney<sup>2</sup> has explained solarisation by the formation of an oxybromide of silver. The question as to the co-operation of atmospheric oxygen in the formation of the latent image has been treated amongst others by Meldola,<sup>3</sup> Tugolossow,<sup>4</sup> and W. Braun<sup>5</sup>. The last from his experiments answered it in the affirmative, and laid down the axiom that "the greater the concentration of the oxygen, the more vigorous the latent image." Braun's most important results must be here briefly stated; according to him gelatino-bromide plates, exposed under a Vogel paper actinometer in oxygen, air, and nitrogen, and then chemically developed, gave a different number of steps, which increased with the increase of the oxygen.

Eder<sup>6</sup> considered that any action of oxygen in the formation of the latent image was extremely improbable, and suggested that contrary evidence of the experiments was required.

Similar experiments to Braun's were carried out under totally different experimental conditions to see whether his axiom was generally valid. It may be as well to state at once that an increase "vigour" of the latent image, with increasing concentration of oxygen in the surrounding atmosphere, could not be proved, either by chemical development or physical development, after fixation.

#### The Gas Dark Slide.

Schaum's sensitometer was used, but the ordinary dark slide was replaced by a special form of dark slide, constructed by Herr Braun, at Professor Schaum's suggestion. The accompanying diagram explains it.

The space for the gas  $R$  was closed in front by the glass screen  $G$ ,  $S$  is the sliding shutter. In the back of the slide was the metal plate  $B$ , and behind this the strip of plate  $P$ , which was pressed

up to the metal cover  $M$  by the springs  $F$ .  $O$  and  $O^1$  are apertures in the sides of the slide, and are diametrically opposite to one another, and serve for ingress and egress of the gas.

#### The Exposure.

In opposition to the experiments of W. Braun I made measurements, not only on dry, but also on wet, strips of plates. I hoped that there would be a better absorption of the gas, and therefore a greater chemical effect than would be possible on the dry plates.

The strips of plates were immersed for ten minutes in distilled water. Greater value must be placed on this soaking, because the plates lose sensitiveness when dampened. It was essential to carry out the work in a room free from the fumes of burning gas, as it is well known that the latter very easily fog a damp plate. The swollen plates were then placed in a dark slide, and a brisk stream of gas passed through the latter for ten minutes, and continued during the exposure. With chemical development the exposure was one minute, at a distance of 1.294 metres, from a benzine candle<sup>7</sup>; for physical development after fixation the exposure was six minutes, to an incandescent gas burner at a distance of 1 metre. To obtain, as far as possible, an even illumination there was placed, in front of the brightest part of the mantle, a metal screen, with an aperture of one square centimetre. The exposure was made alternately in oxygen, air, and nitrogen, in order to avoid errors as much as possible. The gases were obtained commercially, compressed in bottles.

#### Chemical Development.

After three strips had been exposed as quickly as possible, one after the other, the first in air, the second in oxygen, and the third in nitrogen, they were placed in one dish and developed with Eder's normal ferrous-oxalate developer. Development was continued till the first traces of fog were seen. The developer was poured off, the plates rinsed and fixed in a 1:5 hypo solution, and well washed. When dry, the "Schellenwert" of the plates was read by placing them film downwards on white paper, and reading off the last visible number.

In this way a great many of the commercial plates were tested, and out of the whole of the experiments no higher "Schellenwert" could be read on the plates exposed in oxygen than on those exposed in air or nitrogen.

With some plates which were left undeveloped for some time there was, in almost all cases, a formation of fog, which only appeared on the plates exposed in oxygen, and not on those in the other gases. The density of the oxygen plates appeared in consequence of this fog to be greater than on the others.

<sup>5</sup> Zeit. f. Wissen. Phot. 1904, p. 290.

<sup>6</sup> Eder's Handbuch, Bd. I., 1906, p. 258.

### Physical Development.

For this the plates were exposed, as described above, and fixed simultaneously in 1:5 hypo solution. As hypo reduces the latent image, the plates were simultaneously washed, and remained exactly the same time in contact with the hypo. Had the time of fixing not been the same there would have been variation in the results. After well washing, the plates were developed with the metol-sulphocyanide-silver developer, washed, and dried. The number of visible fields remains always the same, whether the plate had been exposed in oxygen, air, or nitrogen. Therefore there is no ground for the assumption that the part of the latent image, more stable in thio-sulphate, can be represented as an oxygen compound.

As already mentioned, experiments proved that the plates exposed dry, and physically and chemically developed, as described above, gave the same results.

### The Effects of Home-made Nitrogen.

In some further experiments nitrogen, prepared in the usual laboratory fashion, was tried. A copious evolution of this gas can be obtained by gently warming the following solution:—

Water .....	90 ccs.
Sodium nitrite .....	10 gms.
Ammonium nitrate .....	10 gms.
Potassium bichromate .....	10 gms.

I noticed the plates treated with nitrogen, prepared according to this method, were fogged, although bichromate was used to oxidise the small quantity of nitrous fumes formed. As a matter of fact, the strong action of this gas on gelatino-bromide can be easily proved. According to my experiments the nitrous fumes developed by the action of nitric acid on copper turnings soon cause solarisation on ordinary dry plates. If the gas is formed by heating lead nitrate to redness the reaction is less evident; in a short time a normal image, but with a longer time a solarised image is obtained.

EDOUARD SCHLOEMANN.

### CATALOGUES AND TRADE NOTICES.

FALLOWFIELD'S PHOTOGRAPHIC ANNUAL.—Difficult as it is to say anything fresh or in higher praise of Fallowfield's list, yet we note one or two additions to the 1907-8 list, which still further add to its usefulness. There is a directory of towns to which the firm delivers free all goods over 5s. value. We see also a useful set of outfits suggested as most suitable for purchasers of different types. In other respects we cannot offer a more cordial welcome to this huge list than to say that it is a triumph of arrangement and classification, and must be as frequently consulted every day of the week by hosts of photographers as by ourselves. The price of the "Annual" is 1s. 6d. post free to any part of the world. There is no better or more complete catalogue of photographic requisites.

A NEW VANGUARD SPECIALTY.—It is hardly within our province to review a new paste for the razor strop which the "Vanguard" Manufacturing Company, of Maidenhead, has introduced, but we may do so on the reasonable assumption that the majority of our readers will find such preparation of occasional service. Its action, in our single experience of it, has been satisfactory.

ROTHERHAM PHOTOGRAPHIC SOCIETY.—The eighteenth annual exhibition of this society is fixed for October 16, 17, 18, and 19 next. In the open section, instead of distinctive classes, the judges will award for "photographs, any size, subject, or school of work" of special merit. No entrance fees. For lantern slides the entry is 1s. per set. There are the usual members' classes. Entries close October 7. The secretary is Mr. H. C. Hemmingway, Tooker Road, Rotherham.

PHOTOGRAPHS OF HOLLAND.—With reference to the exhibition of photographs of Holland, now being held at the house of Messrs. A. E. Staley and Co., a notice of which appeared on page 580 of our issue for August 2, we have pleasure in stating that the entire work connected with the enlarging, mounting, and framing of the pictures was carried out by Messrs. Raines and Co., of Raling, London, W. This firm's work is, of course, known to many of our readers, but others who know it only by reputation should be interested in making a note when at Messrs. Staley's house, of the admirable printing and enlarging of Messrs. Raines.

### WILLIAM MOLYNEUX, ON THE FOCAL CENTRE OF A THICK LENS IN 1692.

IN an editorial note in the BRITISH JOURNAL OF PHOTOGRAPHY March 22 attention was drawn to some early works on optics. A special reference was made to the fact that Dr. Wood, in his "Optics," (1818, but the first edition was 1799) treats not only thin lenses, but also of thick ones, and in the case of the latter makes use of points which he calls focal centres, which correspond to the points we now style "principal points" or "nodes."

In the number for April 5 there is a further reference to the subject, pointing out that Harris (in his "Optics," 1775) had discussed the question much in the same way as Wood, and had treated the subject as if it were already a familiar one to optical students.

It may be interesting, therefore, to our readers of the "Journal" to note that the question of the focal centre of a thick lens was discussed as early as 1692 by William Molyneux of Dublin, F.R.S., who in his "Diotrica Nova," or "Treatise of Dioptricks" (Proposition XXVI., p. 10) demonstrates that in the camera obscura the distance of the object from the lens is to the distance of the image on the white paper screen in the distinct base from the lens as the diameter of the object to the diameter of the image. In doing so he neglects the thickness of the glass, because lenses of large spheres and small thicknesses it is inconsiderable in respect to the focal distance.

He adds the following scholium which may be quoted *in extenso*:—

"But if we are yet more scrupulous and will consider also the thickness of the glass; then the point within the glass from whence the distance of the distinct base is to be counted may be thus determined

a plano-convex glass. In the figure *k d m* is a plano-convex glass, with its convex side towards the object *a b c*; *a d, c d*, the axes of radii cones falling obliquely on the glass in its pole *d*; which (if the glass were not interposed) would proceed directly on to *p*, but the glass are now refracted into *d i, d i'*; but at *i i'*, meeting with second surface of the glass, instead of going straight onwards, they are again refracted into *i e, i g*, parallel to *a d, c d*. Let *e i, g i'* produced backwards till they intersect the axis, *b f*, in *x*. I say: the point in the glass's axis, from whence the distance of the distinct base is to be reckoned. And as the thickness of the glass, is to the distance of this point, *x*, from the inner surface, *z z*, so the cotangent of the angle of incidence from glass to air to the cotangent of the refracted angle.

"For to the point of incidence, *i*, draw *i i r* perpendicular to *k m*. Here the angle of incidence from glass to air is *i d z = i d z'*, the complement of *i d z* is *d i z*, whose tangent is *d z* (making radius), and the refracted angle is *r i e = i x z*, whose complement is *x i z*, and the tangent hereof is *x z*.

"In double convexes the case is something different, but it is needless to enlarge any farther thereon.

"Wherefore we see that if we use a plano-convex glass, with its convex side towards the object, and if we allow for its thickness, are to compute the distance of the object from the pole of the glass, *d*, and the distance of the distinct base from the point, *x*. I suppose the plane side towards the object, *e f g*, then we reckon the distance of the object, *e f g*, from the point, *x*, and the distance of the distinct base, *a b c*, from the pole, *d*, of the glass."

It seems probable that this is the earliest mention of these optical centres in English, but it may be noted that Molyneux refers in his fourth corollary to the same problem (p. 111), and gives its solution in the 52nd proposition of James Gregory's "Optica Promota" (1663):—"The distance of an object and its diameter being given, 'tis required

represent its image in the distinct base under a given measure; thickness of the glass being given also." In this case, however, thickness of the glass is treated as a whole; and no reference is made to an inner point or points as in Molyneux's own problem. It seems to have treated the question in a somewhat similar way (see Hutton's "Mathematical Dictionary," 1815, vol. 1, p. 717,icle lens).

Molyneux's book is of special interest, because it was the first book English on optics, and contains a number of practical problems relating to the use of lenses, theoretically and as applied in the telescope, microscope, camera obscura, etc., as well as a good deal of curious and interesting information on the early use of lenses, etc. pointed out in my paper on "Early Heli-dioptic Lens Systems" (Photo Journal," 26), he has discussed methods of finding the focal length of combinations of concave and convex lenses.

J. WATERHOUSE.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for Patents have been made between July 22 and July 27:—

**LEATHER STRAP.**—No. 17,072. Improvements in or connected with straps or hangers for golf caddie, photographic camera, and other bags or articles. Henry John Carter, 173, Fleet Street, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**THREE-COLOUR CARBON.**—No. 18,741. 1906.—The invention consists in a process of transferring a carbon print to a collodionised plate, attaching a hardened transfer paper to a print whilst still on the plate, stripping it off together when dry, and attaching to the next print. The carbon tissues are sensitised in about a 3 per cent. solution of bichromate of potash for three minutes, then hung up to dry.

To the bath for the blue tissue is added about four ounces of a concentrated solution of picric acid to eighty ounces of about a 3 per cent. solution of bichromate of potash which will turn the blue tissue (which has been coloured with Prussian blue) into a blue-green, which colour will assimilate much better with the yellow and red tissues than the ordinary blue, or the picric acid may be added to the blue emulsion when making the tissue.

All the tissues should be dried in an airtight calcium chloride box, and heat should not be used.

Great care should be taken to cut up the tissue and transfer papers all in the same way, otherwise difficulty may be caused by the stretching of the papers.

Positive prints are obtained upon the carbon tissues from the colour negatives in the ordinary manner. The tissues are then soaked in cold water until limp, and are transferred to glass plates which have been rubbed with French chalk, and then coated with collodion which has been allowed to set, but not dry, and has been washed in clean water. Care must be taken not to put too much pressure on the squeegee used in transferring the tissues to the plates.

The use of French chalk obviates the necessity of employing wax or the like below the collodion, to which there are many objections.

After a few minutes the plates with the tissue on them are soaked in hot water (100 deg. Fahr.) for a few minutes, and the paper on the back of tissue is removed. The prints are then developed and washed.

The yellow print should be fixed, but the blue and red prints should not be fixed, but simply well washed and put to dry. Any good white or tinted double transfer gelatine coated paper is suitable for the final support of the prints.

The transfer paper is soaked in cold water for a few minutes,

then in an about 10 per cent. solution of alum (or a weak solution of formalin) for one minute, is well washed, and is placed upon the yellow print while it is still wet, and the two are well squeegeed together.

When the yellow print has become dry, it and the transfer paper are separated from the glass plate by a sharp knife.

The yellow print having been successfully transferred, the next step taken is with the blue one.

Both the red and blue prints are transferred from the glass plates in the same manner, but a solution made of the following is required to ensure adherence.

To twenty ounces of good size add about half an ounce of Swinburne's isinglass. The isinglass is soaked in water for half a minute and then drained and allowed to stand for ten minutes before adding it to the warm size. The solution is strained and used at a temperature not over 95 deg. Fahr.

The blue print, whilst still on the glass backing, is placed on a levelling stand, and the solution is poured over it. The yellow print, previously soaked in cold water, is placed on the top of it, then slightly squeezed.

The two prints can be registered by looking through the glass of the blue print. The prints are dried on the glass plate and are then separated from it as before. The red print is transferred in exactly the same manner as the blue.

It is advisable after the red print has been transferred to paste a piece of double transfer paper which has been soaked in alum (or formalin) water, and then washed to the back of the print on the glass with the gelatine outside. This will keep the finished print flat when it is detached from the glass.

If any of the three prints appear to be too dense when temporarily superimposed they can, if not over-printed, be reduced by gently rubbing with cotton wool and methylated spirit. Albert Davies, 65, Durnford Street, Stonehouse, Plymouth.

**SCREEN PLATES FOR COLOUR PHOTOGRAPHY.**—No. 20,834. 1906. This invention relates to improvements in the manufacture of screens and plates for obtaining photographic pictures in colours of that class in which a series of transparent filaments of the required colours is mounted on a transparent base. The invention consists in producing photographic screens and plates, comprising a sensitised emulsion, coated over a coloured pigment net or base, and in an improved form of such net or base in which the coloured particles are arranged symmetrically over the whole surface.

For forming the net or base a number of the transparent filaments, which may be of silk, cotton, flax, cellulose, etc., are employed. The net is produced by one of the following processes: For example, to form a fabric there is used as weft and warp alternate filaments of each of the three colours, or, as weft and warp alternately, a filament of each of the three colours, leaving the filaments of opposite direction (warp or weft) in white or non-coloured silk; or a fabric may be used the warp of which is dyed with one of the three colours, the weft with a second of such colours and the interstices thereof filled with a coloured material making the third colour. The filling of the interstices and consequently the production of the third colour of the net, may be obtained in any suitable manner, either by means of a coloured powder, or preferably by using a suitable coloured gelatine or varnish.

In the case of an assemblage of filaments without weaving or interlacing, a band formed by the linear juxtaposition of homogeneous filaments, alternately coloured in the primary colours, may be employed, and stuck to each other or embedded in a heterogeneous medium.

This latter means of preparing the coloured net or base permits of obtaining on the plates, not only coloured negative images of the objects photographed, but also positive pictures in colours by printing with white light through the coloured negatives prepared similarly to those used in ordinary photography.

The plates are usually rectangular, and the threads are so placed that they are parallel with the shorter sides of, say, the positive and with the longer sides of the negative. The linear arrangement of the colours on the two surfaces then automatically assures the superposition of the dyes of the same order at all points of intersection of the filaments of the same colour; moreover, the refraction of the light in the monochrome

filaments, when each filament is exposed within the exact limits set by the filaments of complementary colours, causes the haloid silver salts to be reduced over the whole length exposed, and thus ensures the quality and purity of the shades.

In order that this latter phenomenon shall be as distinct as possible, filaments of single thread or ply, approaching as nearly as possible to the required optical conditions, must be used. The net or base may be directly laid on plates or on pellicles by means of a roller, and the selective filter thus obtained we have termed "a chromo-film."

The production of the "chromo-film" is as follows:—

In practice, the coloured filaments on leaving the spools and after sufficient drying are placed on slightly conical rollers, which, by rotating and sliding the threads along the generating line, bring them into contact. The contact is made more perfect by moistening the filaments with a viscous liquid, such as glycerine or dissolved gum arabic, and by causing them to travel over a polished cylinder, the tangential velocity of which is slightly greater than the velocity of the filaments. Capillarity then ensures intimate contact without overlapping.

Seen with the naked eye the resultant film appears absolutely neutral, if the pigments are properly selected, but under the microscope the fine striæ in three colours are visible. This film forms a perfect selective filter.

The chromo-film described can be used in the manufacture of photographic plates, for the production of photographic prints in natural colours, according to the nature of the panchromatic emulsions used. The chromo-film is applied to a layer of emulsion between rollers or the like before the gelatine has completely hardened.

The glass plates to which the screens and emulsions are applied are prepared and washed in the usual manner. When the glass has been dried it is coated with a solution of mastic in benzene, and the practically instantaneous evaporation which takes place leaves the glass coated with a very thin and adherent pellicle. On the latter a solution of caoutchouc, which dries very slowly, is spread in the manner usually employed for spreading gelatine. After being allowed to dry spontaneously for a period of two hours the caoutchouc layer is ready to receive the chromo-film or fabric.

The fabric preferably used is very close muslin, dyed in the usual manner with a very fast mordant, and of rather dark colour. If necessary the fabric may be sized to prevent the adherence of foreign substances to the silk during the subsequent treatment. The screen is applied to the caoutchouc-coated glass, adherence being produced by applying suitable pressure with the aid of a soft roller.

If it is necessary to fill the interstices of the fabric with a pulverised substance, the filling is effected after the fabric has been applied to the glass and before the caoutchouc layer has become quite dry. A soft rotary brush can be used to remove the superfluous powder.

If the interstices are filled with gelatine or with a coloured solution containing a ferric, chromic, or other sensitiser, which gives a coloured reaction under the influence of light, the third colour is obtained by the photographic exposure through the screen, the threads of the fabric protecting the gelatine directly behind them.

The screen is varnished when dry, either with wet or with pulverised varnish, and the emulsion is applied when the varnish is dry. Highly sensitive bromide emulsion, with or without iodine, is used, the emulsion being rendered panchromatic and applied in the usual manner.

The material required for using the plates differs only very slightly from the materials ordinarily used. A coloured screen is placed in the path of the rays, in front of, behind, or within the objective, if the panchromatism of the emulsion is not perfect.

Several successive and distinct operations are involved in the subsequent treatment—viz., developing, inversion of the picture, if a direct positive is to be obtained, and fixing. Rodolphe Berthoin and Joseph Gambs, 8, Place des Jacobins, Lyons, France.

MAGAZINE CAMERAS.—No. 16,253. 1906. The invention consists of a type of camera in which the plates are carried in a magazine

which can be raised on a pivot, *y*, so as to afford a clear of the focussing screen. The latter, *c*, is fixed in grooves attached to the quadrant shields (*b*) of the magazine, so that by movement of the mechanism the magazine is raised, and

focussing screen is simultaneously brought into position shielded from side light. Octave Edouard Jules Joublin, Harper Street, New Kent Road, London, S.E.

## New Trade Names.

MOORLAND.—No. 292,534. Photographic papers and posters. Harold Arthur Blades, The Central Pharmacy, 1, Stanley Street, Leek, Staffs, dispensing and photographic chemist and druggist. April 29, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Blisters in Carbon Printing.

A good deal of difficulty may be avoided (says a writer in "Photographic News") by a careful selection of transfer paper. If surface is what is desired, choose a thinner paper in preference to a thicker one, the thinner paper being easier to saturate with water prior to squeegeeing down the exposed tissue. A fairly soft paper is preferable to a very hard one, less vigorous squeegeeing being necessary to secure perfect contact over the minute inequalities of the paper surface. The character of the gelatinous sizing should also be noted, and it is well to soak a sample of the transfer paper in water, say at a temperature of 130deg. F., and notice carefully the gelatine behaves. After some little time the transfer paper may be taken out of the water and surface-dried between blotting-paper and the gelatine rubbed with the ball of the finger. If it remains firmly on the paper it will probably work satisfactorily, but if it readily rubs up almost in a moist, powdery way the transfer paper may be regarded with suspicion. The gelatine is poor, or has been allowed to remain heated for too long a time when the sizing has been done. Better a little additional sheen on the surface of the print than no print at all on account of blisters.

### Vignetting a Portrait.

One of the cases in which it is likely that the photographer will want to use the glycerine method of control in platinum printing (says a writer in "Photography") is to get a good, bold, sketchy vignette effect in a portrait. The whole of the face and other portions that are to be fully shown are first brought out to their proper depth, and not until this has been done is the vignetting properly undertaken. Then, with such admixture of developer and glycerine as the circumstances seem to dictate, the lighter parts of the vignette are brought out. By a series of strokes with the brush, one going a little further than the last, we shall find it possible to develop up an image gradually getting fainter and fainter towards its margins, yet without showing by any defined lines where the fading off in depth has taken place. When this has been done to satisfaction, we may still wish to add a few more decided brush marks, and this we can do with developer containing a smaller proportion of glycerine, or even none at all. But as such application

only develop up an image if there is one there to develop, we find that without further help the effect we want is not to be. In such a case, we may put down over the greater part of the surface a piece of black paper rubbed with glycerine, and then expose the print to light for a little while, so that the unprotected parts, which, however much they may be coated with glycerine, are still sensitive, may be so far affected that they will develop up black if required. It is well to cover the print with a piece of glass while doing this, and to shade it so as to avoid a dark line at the edge of the black paper. Drastic as such treatment may seem, it will do no harm if the developer has been properly removed from the finished prints and glycerine substituted. After the light action, we may remove the glass and the black paper, so as to see what we are about, and add such further work as seems necessary, remembering always that every brush-mark now will no longer develop up in correct relation with the rest, but only as a dark mark.

### Dark Slides for Hand-Camera Work.

Dark slides with hand-cameras (writes Mr. J. H. Crabtree in *Focus*) are, at times, a decided advantage. We may have two slides with iso. plates, two with extra rapid plates, and two with plates of moderate speed. We can now choose any plate we find most suitable for a specific purpose—the moderates for open landscapes, the iso. plates for clouds, and the extra rapid for quick-moving objects. Every hand-camerist knows well the importance of being able to select his plate. But we have such a knack of forcing which plate has been exposed. Here is a "tried" wrinkle:—on each side of the plate-holders paint in white a large figure, indicating the number of the plate, and with a black-lead pencil make a cross on the white figure when the plate has been exposed. This is done in a moment, needs no book, no list, and is certain. When the plates are removed for development cancel the crosses. You may use each figure to hold at least twelve crosses; they may be easily erased by means of india-rubber.

## New Books.

and the Camera." By Antony Guest. London: Geo. Bell and Sons. 6s.

This would prove an excellent book for photographers who suffer from sleepless nights. Kept within handy reach, its soporific qualities could not fail to induce the coveted snore of obliviousness. That it is a bad book as such books go; but it trots on, up and down, through thick and thin, without anything more than a misprint or an orthographical lapse to relieve the soothing monotony.

I say that there is no need for such a book is only to repeat what might be said of hundreds of other books published nowadays. A poor old Art seems to be fair game for anybody, qualified or otherwise, who wants to raise a few pounds by making a book. Photography, so far as it is concerned with art, is similarly doomed. Small public could, no doubt, be found who would buy Mr. Guest's book and take no harm by reading it; but to the majority of photographers it will be but cold kail, or, more correctly, a piping up of stale fare from the photographic weeklies. Articles, reviews, correspondence in the Press, discussions, all have had to matters for subject over and over again. Hence the book has little originality of thought on the part of its author. But young lady in the country, if she does not take a photographic interest, will probably value it highly. Its closing page or two, in the author pleads, with his usual *juste milieu* attitude, for analytical and synthetical methods, is distinctly good.

Mr. Guest trims his sails too constantly, and to all quarters, not, indeed, to the professional photographers, for whom he has a charitable word. Presumably he considers this the safe and prudent line to pursue in the circumstances. Even to the "arty" crafty movement he makes his profoundest obeisance.

In the art-crafts a thing is reckoned beautiful because it is useful, and has been fashioned simply and exactly to meet the purpose for which it is intended, with no ornamentation for the mere

sake of ornament, but with due sense of design, and such adornment as may result spontaneously from the craftsman's pride in his work, and from the character of his material and tools."

We quote this to show how easily the author allows his subject to trot nicely away with him. If every term in the extract were reversed, something like the truth of the matter to-day might be derived, for the Morris ideals were buried and lost years ago.

Mr. Guest is given to perverting fact in that way. Here is another example:—

"Something more vital has been wanted than fashionable professional portraits and trade views of scenery, and it was this need that led to the formation of the 'Linked Ring.'" To which we can only remark, "Was it, indeed?" Here is another crystal gem of truth of the first water:—

"The Royal Photographic Society has been tempted to follow the example of the Salon by holding an annual exhibition of pictorial work."

A propensity to construct theories out of his own conclusions is a marked defect of the author, leading him into such quagmires as, "Training is an assistance, not an essential." This little aphorism, denied by all life and experience, is vamped up to support the photographer's claims to rank as an artist. It rests upon the common blunder of confusing the final achievement of a thing, as implied in the noun "artist," with the leaning toward, or the propensity for, a thing, as implied in the adjective "artistic." School-training or self-training is as indispensable to an artist as it is to a scientist. Only those who actually work to some purpose in any branch of art know how enormous a part is played by training, mental and physical. All the cant about soul and inspiration is so much popular rubbish. Mr. Guest and writers like him have much to answer for, inasmuch as the unthinking button-presser, otherwise sane and modest enough, comes to think himself the equal of any artist by reading year after year such empty flattery as the passage commencing: "Nor does it follow that those who are trained in art are the only artists."

So far we have said nothing of the illustrations of this work. As a matter of fact, they are an unimportant feature, since everybody who has preserved his weekly papers has them in duplicate or triplicate, and much better printed. For some reason or other (something with "art" in it, no doubt) the pictures are given in faint shades of grey or brown, regardless of their subjects, and utterly without regard to the tone of the originals. "Washed-out" is the sole term that describes them suitably. The only prints that have not suffered much are the sea-pieces by Mr. F. J. Mortimer. His "Peace" has quite a fine fog effect. But where was the necessity for fog in Mr. Horsley Hinton's "Melton Meadows"? We are sorry for Mr. Evans, whose "best picture" in York Cathedral is itself a magnificent ruin, as flat as wallpaper. As for Mr. Arbuthnot's "Road to the Farm," it is ridiculous. Mr. Guest thinks it "apparently simple, but really very subtle."

There are 150 pages in good-sized type, and thirty-nine enfeebled pictures, and the price is 6s. The proofs seem to have been carelessly read, otherwise such tautology as "visual appearance" would surely have been looked to, to say nothing of "judgement," and other little trifles that waken the reader, with unpleasant jarrings, from out of the nodding state induced by the moderate opinions, the obvious platitudes, and the pretty compliments on the illustrations, uttered in rubber-tired phraseology. We wish the book well.

"The Half-Tone Process." By Julius Verfassers. Fourth edition. London: Iliffe and Sons, Ltd. 5s. net.

That there is a constant demand for a good book on the half-tone process we are constantly reminded by the inquiries we answer through our correspondence columns, and so we are not surprised to find that "The Half-Tone Process," by Julius Verfassers, has reached a fourth edition. In preparing this, the author has thoroughly revised his matter, and brought the book entirely up to date, with several additions. Though much of the book is taken up with descriptions of apparatus which are tedious reading to those familiar with the process, or those who have prejudices in favour of one sort of thing rather than another, nevertheless we must remember that the book is not written for them, but for the man who only knows about ordinary photography, and wishes to know something of half-tone work. Certainly, if his intention had

been to commence business in this process the quantity and expensive character of the apparatus described is calculated to deter him, unless he is prepared for a large outlay.

The opening chapter, "What is a Half-Tone?" is an admirably lucid answer to the question, an explanation assisted by excellent diagrams. The second half of the book, describing the operations, is also exceedingly interesting, and while we think that perhaps the author's claim that "the reader will find in the book everything it is necessary to know for practising the half-tone process," is a little extravagant, we are inclined to agree that there is as much as one can expect in a book on the subject. Throughout the Continental and American methods are compared with English ones; there is a chapter on three-colour work, and also one on the preparation of originals, all formulæ are given in both English and metric weights and measures, and in the practical quantities of either one pint or one litre, and finally there is a full index. We can thoroughly commend the book.

"Hints on the Selection of Zeiss Objectives." By Dr. P. Rudolph, Jena. Fifth Enlarged Edition.

This is a most useful pamphlet that all prospective purchasers of Zeiss or indeed any lenses will do well to consult. It enumerates the various uses to which photographic lenses are put, and describes the particular kind of lens that is best suited to each purpose. Many useful rules are given, together with reasons, and Dr. Rudolph's name is sufficient assurance, though the reasons are sound ones. For the hand camera we are advised "always to choose a lens so as to have its focus neither considerably longer than the diagonal of the plate, nor appreciably shorter than its longest side." It is then pointed out that while these limits determine the view angle as from 50 deg. to 70 deg., yet "in order that an image of that angular extent may not exhibit a too glaring decrease of light from centre to margin, it is desirable to have an objective whose field is largely in excess of that estimate. Hence objectives having a field of from 65 deg. to 90 deg. are the most suitable." Advice is given respecting the selection of lenses for a one-objective outfit for a stand camera, for a set of objectives for a similar camera, and for stereo cameras. It is pointed out that if one used single protars for the stereo work, the same two lenses can be screwed into one mount to form a double objective for panoramic wide-angle pictures, which can be produced in the same camera.

Lenses for three-colour work are also considered, and a good example of a three-colour portrait is given, together with some excellent examples of work in monochrome.

Though the book deals only with Zeiss lenses, it does not leave us with the impression that it is a mere advertisement. There is a refreshing absence of puff in statements such as the one explaining that, as regards orthoscopy, "Single lenses with frontal stops still leave something to be desired." It is evident that the pamphlet is intended to so advise the purchaser as to render him capable of selecting for himself, and also to give him useful information of a kind that he often cannot obtain from a salesman.

"THE PHOTO-MINIATURE."—No. 8 of this periodical (Dawbarn and Ward, 6d.), concerns itself with the practice of outdoor photography, on which topic of the present season it has a good deal to say which will run no risk of being hailed as startlingly new, which is, indeed, old enough to be worthy of occasional resuscitation. The writer's notes on how to photograph the common objects of town and country—from a motor-car to a moonrise—are sufficiently brief to be rapidly digested. The "Miniature," we are glad to see, is redeeming its promise of regular publication. Its next number is to deal with modern novelties in printing processes—kallitype, ozobrome, and, of course, oil.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The usual quarterly dividends of  $1\frac{1}{2}$  per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of  $2\frac{1}{2}$  per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, have been declared by the Eastman Kodak Company of New Jersey; also an extra dividend of 5 per cent. upon the common stock, payable on October 1 to stockholders of record at the close of business on August 31, 1907.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 10.

Borough Polytechnic Photographic Society. Outing to Southfleet.  
Bowes Park and District Photographic Society. Outing to Zoological Gardens  
Bristol Photographic Club. Outing to Frome.  
Devonport Camera Club. Outing to Fice's Well, Mis Tor, Langstone Moor Ch

A. H. Lisett.  
Leeds Camera Club. "Mounting and Framing." A. Cohen.  
Rugby Photographic Society. Outing to Frankton Woods.

## Commercial & Legal Intelligence

CHARGE OF EMBEZZLEMENT.—John Hy. Preece, photographer, charged at Middlesbrough last week with embezzling sums amounting to £6 5s., the property of Arthur Rollin, 17, Shields Road, Newcastle-on-Tyne. The prosecutor said that he carried on a photograph business at Newcastle, and opened a branch shop at 18, Wi Street. The shop went by the name of the American Studio, prisoner was engaged by witness to develop and touch up negatives to look after the money, and generally to supervise the business Middlesbrough. His salary was 35s. a week. Prisoner's arrangement was to send in an account every Saturday evening showing financial position for the week, and enclosing the balance money order. On July 19 witness received a letter from prisoner asking for a loan of 50s., and enclosing a crossed cheque post dated July 22 witness received a correct statement of the transactions, only on an order for 7s. 6d. instead of £6 5s., the correct amount. Witness came to Middlesbrough and found that prisoner absconded. He afterwards received by post from prisoner a post order for 5s. 1½d. in part payment. Prisoner pleaded that he did intend to defraud. The Chairman told prisoner that his downfall was evidently due to gambling, and but for the excellent testimony produced in his favour the Bench would have sent him to prison. A fine of 25s. or one month was imposed.

## Correspondence.

"\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

### GLAZING A STUDIO.

To the Editors.

Gentlemen,—An inquiry in the current issue of your journal, dealing with the best way to glaze a new studio (or to reglaze an old one for that matter) prompts me to send you particulars which may be useful to your correspondent or to others who may be troubled with leaky roofs.

Last Whit Monday I entirely removed the old roof of my studio

placed with steel bar, a drawing of section of which is given. This is only a little less than actual size of bar, and can be used by Mr. Sam Deards, Victoria Works, Harlow, Essex, who will be pleased to send full particulars to any enquirer, as to me. The advantages of the system are numerous—easily absolutely rainproof, no putty or other material, and prac-

indestructible; very little stoppage of light, neat in appearance and cheap.

I can add I have no interest whatever in Mr. Deards, but I here must be many photographers who would be as glad to have the improvement as I was.—Yours faithfully,

The Grove, Hammersmith.

GEO. E. ORGAN.

## Answers to Correspondents.

Matters intended for the text portion of the JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photocraphs at a charge of 1d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the

SKIN AFFECTION.—I should be pleased if you would give me an answer to this question in the next publication of your Journal. I am a printer here, and I do a lot of bromide work; use a lot of gaslight papers. In developers for these I use amidol and metol. I have only been using same for a week, my hands are very bad indeed. There are little white scales come; they burst, and a kind of liquid like water comes from them. They are rather painful, and my fingers have swollen a little; it is mostly between the fingers; not at the ends, but right down. Can you tell me how to cure this, or, how to prevent it? I should be much obliged if you could.—A. T.

As is evidently the case, you are susceptible to metol, there is nothing for it but to discontinue its use. We know of no preventive measure. We should advise you to select another developer. Amidol is not, as a rule, a cause of these troubles.

AGREEMENT.—So far as we can make out from your letter, the agreement seems to be a very loose one; verbal agreements are of little value. The best advice we can give you is to consult a solicitor at once, tell him the arrangement made, and show him your letter you have, which you call an agreement. We should recommend you to do this without delay.

ANSWERS.—I heard from a friend that you had lately published, in the "Answers to Correspondents" column, an answer to an inquiry about transferring photographs on watch-cases, etc., by the C. process. You said that the directions were to be found

in a "B.J. Almanac." Have you a copy of it that you could supply me with? If not, where could I obtain one, and what year was it dated?—W. ALLCHIN.

The method of producing photographs on watch-cases and the like by the collodio-chloride process did not appear in the "Almanac." It was fully described in an article that appeared in the "Journal" for 1901, p. 451. Full working details are there given.

PHOTO RELIEFS.—Can you please tell me how to take plaster of Paris casts from gelatine reliefs. I can make the reliefs all right, and they have a high relief, but my difficulty is with the plaster cast. I slightly oil the relief and then mix the plaster with water to a thick cream, and then join on. It takes some hours to dry, and then when I try to get it off it all breaks to pieces.—RELIEF.

The trouble is, apparently, entirely due to the plaster of Paris. The plaster for this purpose should be of fine quality and freshly burnt. That sold at oilshops, in bags, is not at all suitable for making what you desire. You should get the quality used by those who make plaster figures. Any of them will supply you with some, but you will have to pay more for it than that you get at the oilshop.

R. J. BILLING.—The only way to recover the debt is to sue the secretary of the club—or, rather, the one who gave you the order to photograph the group—in the county court. If it was the secretary of the club who gave the order it is him you must sue.

T. A. SMITH.—It is not photographers who can prosecute in the matter, but only those who have been swindled out of their money, and you have not. All you can do is to bring the people prominently to the notice of the police and get them to take action. We hope you will do so, if the facts are as stated.

RESIDUES.—I have been for some time past saving my wastes, print washings, burnt prints, etc. I have now got about half a pound quite dry. What had I best do with them?—AMATEUR.

We should say save them until you have accumulated a sufficient quantity to make it worth while to send it to a refiner to deal with. Such a small quantity as you now have certainly is not.

SURFACE PAPER.—I want half a quire or a quire of enamelled paper, such as is used for P.O.P. Will you please tell me where I can get it? I have applied to several dealers, and they all say they do not keep it.—FIRM.

Messrs. Otto König and Co., Cross Street, Finsbury, supply it, but we think only in wholesale quantities—reels weighing, perhaps, a couple of hundredweights each. They might, however, let you have a small quantity in sheet. Better write them.

METOL POISONING.—One of my men, an assistant operator, has been unable to work for the last two or three weeks through the metol developer badly injuring his hands—and they are bad. His wages are 35s. a week, and he tells me I am compelled, under the new Act, to pay him half his wages until he is well enough to resume his work, and that unless I do he will summon me for it in the county court. Can I be made to pay, as the man has been of no use to me for nearly a month?—W. J.

The man is quite within his rights, and you will have to pay him half his wages. If your employees are insured, the insurance company will, of course, meet the claim.

AN OLD LENS.—A little while ago I bought a whole-plate lens of Voigtlander's at a pawnbroker's. It seems to have no focus at all. My 10x8 camera focusses from 7½in. to 24in., and I cannot get any image at all with the lens. The front lens is 3½in. diameter, but the back is less than 2½in. On the mount is an engraved scale, with about 1-16in. divisions. Can you tell me what is the matter with the thing, and how to put it right?—R. BOLTON.

From the description we recognise the lens quite well. It is not a whole-plate lens at all, although the mount is the size of one. This form of lens was made by Voigtlander in the early days of the Daguerreotype process for taking small portraits of

children very quickly. We are not at all surprised that you do not get an image with your camera, as the back focus of the instrument is but about 3in. It is only intended for small pictures, locketts, and the like, and might be used for midgets. The exposure required with it is only about the fourth that of the usual portrait lens. The visual and chemical foci do not coincide, and the object of the scale is to show how much the lens should be racked out after the visual focus has been obtained to get it in the chemical focus.

**WORKMEN'S COMPENSATION ACT.**—Will you please let us know, in "Answers to Correspondents," if it is really compulsory to insure our assistants under this new Act, and what is the fine for not doing so? We employ ten assistants and apprentices and an errand boy, and to insure them would be an item that would increase our expenses, and we have to cut them fine, as ours is only a cheap business.—C. J. AND CO.

It is not compulsory to insure your assistants, and there is, of course, no fine for not doing so. The responsibilities of employers under the new Act are so great that most photographers recognise the advantages of insuring. The insurance companies undertake to pay any compensation for injuries that employees may meet with during their work, which the employer would otherwise have to do.

**COPYRIGHT ("ILL-USED").**—If the father ordered the portraits of the children to be taken, although you cannot get payment for them, the copyright in the pictures is his, and not yours, even if you register it. The father, in ordering the portraits to be taken, incurred a debt which you may recover in the county court, and in these circumstances, according to the decision in the *Boucas v. Cook* case, the copyright is vested in the father.

**CARBON PRINTING TROUBLE.**—Will you please suggest the cause of my difficulty and how to obviate it? I am trying to work the carbon process. I sensitise the tissue for three or four minutes in the following: Bichromate of potash 1oz., water one pint, with six drops of ammonia, then slightly squeegee on to a ferrotype plate and allow to dry. The drying with me takes twelve to fifteen hours before I can get it off the plate. After printing and squeegeeing on to the single transfer paper, the tissue will not adhere. I have soaked it various times, but all with the same result.—BEGINNER.

The cause of the trouble is that, through the long time taken in the drying, the tissue has become insoluble. You should manage to dry it in six or eight hours at most by crying in a drier place than you have hitherto done. Failing to obtain that, we should recommend you to try the spirit sensitiser now being sold by the Autotype Company. We might mention that the bichromate solution you have employed—5 per cent.—with the long immersion you have given, is too strong for this time of year, unless you have exceptionally hard negatives to deal with. Three and a half per cent., with a couple of minutes' immersion, would be better.

**STRAW BOARDS.**—As one of your regular readers of the "B.J.," I should feel much obliged if you would kindly give me the address of two or three firms who manufacture straw-board postal tubes? I have looked through the trades directories here, but cannot find any.—J. T.

Try L. Canesi and Co., 16, Clerkenwell Green, E.C.; Oram and Robinson, 2, Academy Buildings, Hoxton, N.; and Arundel and Marshall, Penn Street Works, Hoxton, N.

**EASELS.**—Will you kindly give the names of firms where carved easels may be obtained?—W. H. DEE.

Marion and Co., Ltd., 22, Soho Square, W., and J. Barnard and Son, 19, Berners Street, W.

**SULPHITE IN DEVELOPERS.**—Some time since attention was called in your columns to the preservation of sulphite soda in solution, and at various times since remedies have been suggested, but they all seem to tend to an excess of metabisulphite of potassium. My experience of this—say, a 1 to 4 solution—is that when freshly made up it is slow, and needs much more pyro, and also that it does not keep. I made up some—soda sulphite 4oz., metabisulphite 1oz., water 20oz.—about three months ago.

Upon using same a few days since nothing but a very faint image was the result. I increased the exposure to four minutes (interior work), but still could get nothing satisfactory. I made up fresh sulphite soda solution with 4oz. metabisulphite instead of 1oz. With this an exposure of 15 seconds gave rather over-exposed negative! I think I saw in the "B.J." some weeks ago a suggestion of yours to use spirit as a preservative. Is this any good, or has anything else been found to preserve sulphite in solution, say, for three months without losing its power? My developing is at irregular intervals, and owing to the varying power of the sulphite I lose many plates. I sometimes want it at short notice when there is not time to make up a fresh lot; there is also the waste of throwing away half three-quarters of the old solution. I much prefer the pyro on account of it being so much cleaner than ammonia. I do not know the action of the sulphite in the developer, and do not know if an acid or alkali should be looked for to preserve it. I may add that I find 1 drachm metabisulphite in 1oz. pyro mixed up to 20oz. keeps well for several months in a corked bottle.—W. E. M.

The formula you refer to was stated to be slow. If you increase the pyro and the carbonate the slowness is remedied but development generally takes from five to ten minutes. Slowness does not denote want of keeping power—rather the opposite. Metabisulphite is perhaps the best possible preservative for sulphite. Alcohol is a good preservative, but we do not know if the sulphite preserved with it will be much good for development at the end of three months. A little metabisulphite will probably be more effective, but we are not at present able to state the minimum quantity that will serve. These matters that we hope to experiment upon shortly. For use as an emulsion, a mixture of sulphite and metabisulphite seems to last indefinitely, and though the conditions with pyro are somewhat different, we have found the same solution to serve well for six months. A good deal depends on the quality of sulphite used. Not very much is known with regard to the preservation of sulphite, but it seems to keep best when no alkali is present. In a few months we may have more information on the matter.

**W. C. E.**—J. Epstein and Co., Rupert Street, Bristol; the Birmingham Moulding Warehouse, 48, Great Hampton Street, Birmingham; Frost and Reed, 8, Clare Street, Bristol.

**REDUCING INTENSIFIED NEGATIVE.**—In the case of a negative which is too contrasty by re-development-intensification, can it be reduced by persulphate or sulphite of soda? Kindly recommend the treatment and oblige.—G. H.

Reduction with persulphate is apt to be irregular in such circumstances. If we understand you to have used a developer after bleaching, we should advise you to repeat the process, taking care to stop the process at an earlier stage.

**BLUE PRINTS.**—Would you be so kind to let me know whether ferric prussiate prints are as permanent as other papers, and you greatly oblige.—F. R.

They are fully as permanent as any other print; in fact, blue print is one of the most permanent forms of photography.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

## SUMMARY.

sentence of three months' imprisonment for theft was passed at  
 row last week upon an enthusiast in pictorial photography.  
 offender had taken part in competitions and received awards in  
 shape of gold and silver medals. (P. 624.)

y. Pirie MacDonald explains his very simple adaptation of the  
 index system for keeping a watch on business which is in danger  
 slipping from the photographer's hands. (P. 615.)

case in which a claim for wages was made against the managers  
 factory which had stopped working was heard before the City  
 h last week. (P. 624.)

rther canvassing frauds, and robberies by canvassers, are  
 ted on page 623.

e refer on page 611 to certain practices and styles as regards  
 grounds which may repay revival.

ans of alleviating or preventing the metol skin disease are men-  
 d by two correspondents. (P. 624.)

. F. E. Ives has recently described before the Franklin Institute  
 fraction colour-meter. (P. 619.)

e only patent of the week is for a stand for the cinematograph  
 ctor. (P. 621.)

ne hints on colouring photographs with water-colours have been  
 shed by an American worker. (P. 617.)

. A. J. Anderson, writing on the use of a long-focus lens in  
 camera photography, makes a strong case against the normal  
 length of 5 in. on a quarter-plate. (P. 612.)

e Lumière Brothers have recently found that the theory of  
 on with hyposulphite does not apply equally to the different  
 ounds of silver. Their experiments again show the danger of  
 ing the fixing bath to the point of complete exhaustion. (P. 614.)

ne curious phenomena of marine photographs taken against the  
 appear to afford some explanation of the formation of water  
 ss. (P. 610.)

## EX CATHEDRA.

### The "B.J." Almanac, 1908.

Next year's volume of the "British Journal Photographic Almanac" is already the object of our immediate care, and we are at the moment looking forward to seeing a large proportion of its pages accumulate on our table between now and the end of September. In quite a number of respects the "Almanac" will be remodelled and brought up to date. One of our endeavours will be to save space without sacrificing matter, in order to co-operate with our publishers in reducing the bulk of the volume and making it more conveniently handled by both the reader and the distributor. In general, however, the arrangement of the current issue will be maintained, and no effort relaxed to make the "Almanac," as before, the most complete record of the photographic progress of the year, not only in technical matters, but as concerns the trade and business of photography. The practical formulæ section of the "Almanac" will also be revised, so as to bring it into line with the latest approved practice.

\* \* \*

### Pageants and Business.

There is no question that the pageants which seem to have been the order of the day during the past month or two have brought much business to photographers. They have also served to illustrate the enterprise of some photographers: for example, photographic reproductions of most of the scenes have appeared in the press the following day, and cinematograph pictures at the music-halls the same night; and within a day or so the different places where the pageants have taken place have been flooded with postcards depicting the various phases of the processions. Yet in many instances the cards are not the work of local photographers, but of enterprising London firms, who sent down operators specially to take the pictures. The local men, in most places, have been at work, and have obtained excellent results; but they did not get sufficient pictures on the market to supply the demand before the outsiders' supply came to hand, and, in many instances, at a lower price, much to the loss of those on the spot. We have more than once commented on the lack of enterprise amongst provincial photographers in the matter of the publication of postcards of local scenes and events. All these pageants should have proved a rich harvest to the photographers at the places at which they were held, but we fear that many have not profited by them to the extent they might have done had they been more energetic and enterprising, and so forestalled the outsiders.

\* \* \*

### Electricity Dangers.

Many photographers who now employ the electric light, and probably many who may adopt it in the future, understand very little of

electricity, and the risks they may run. The annual report of the Chief Inspector of Factories and Workshops, recently issued, shows the necessity for more caution being exercised by those employed in the installation and working of electrical machinery and plant. This report refers more particularly to generating stations and the like, but it should be stated that it applies equally to all places where the current is employed, even in photographic studios. At the present time the current supplied by most of the companies is of a much higher voltage than was the case a few years ago. Two hundred volts is now very general, and though hitherto that has not been looked upon as being at all a dangerous one to deal with, yet quite recently we read of a workman who was running wires for a temporary light being killed by a shock to earth of only 200 volts. Evidently the man was somewhat incautious, inasmuch as a current of that pressure is not considered actually dangerous, but only one that would give a severe shock. Mr. Henry Van der Weyde, who was about the first in London to adopt the electric light in portraiture, and who used a hand-feed lamp, always made it a rule when manipulating the light to keep one hand in his pocket, so as to avoid all risk of getting a shock, although he did not employ a voltage of anything like 200 volts—probably not half that. Still, at that, a shock, though not dangerous, is decidedly unpleasant. Photographers who employ the electric light will do well to be very cautious, and not touch any wires that are not thoroughly insulated.

#### The Late Exhibition of the Royal Academy.

The Royal Academy having closed its doors last week, we learn that the attendance during the time it was open was about the average—a testimony to the position of the R.A. Exhibition in social life of all classes rather than to its "artistic" character. So far as the exhibition is concerned there was nothing very exceptional in it, as there sometimes is. Sales, we learn, have been below the average, particularly in the case of the higher-priced pictures. The highest price, we are told, paid for a single picture reached four figures—viz., one thousand pounds, for Mr. L. Campbell-Taylor's "The Rehearsal." Several of the pictures which met with the highest approval of the Press critics remain unsold, and many of those that did meet with sale have not realised what their painters fixed as their value. It seems that at the present time modern pictures are more or less a drug in the market, as witness the small prices fetched at recent auction sales by those for which a few years ago large sums were paid. It seems that, at present, the only pictures for which high prices will be paid are those by the old masters, as will be seen by the almost fabulous sums that have been given for them at auction sales during the past year or two. This does not seem a very promising outlook for rising painters, whose only consolation appears to be the possible, and sometimes remote, contingency that a few centuries hence their pictures will be changing hands at the price of a king's ransom.

\* \* \*

#### Some Applications of Ozobrome.

The following suggestions by M. Coustel in the "Photo-Gazette" are decidedly worthy of trial, and considerably increase the usefulness of this process. If one has a thin negative that requires intensification, we can use the ozobrome process. A sheet of the pigment paper should be immersed in the sensitising solution and squeezed into contact with the negative. If the negative is somewhat hard, it is advisable to increase the strength of the sensitiser and

reduce the time of contact. If, on the other hand, negative is soft, then the sensitiser should be reduced in strength and the time of contact increased. When carbon image has been developed, one may either dissolve out the original silver image or re-develop it. If the tensification given by the superimposed pigment image is insufficient, an easy remedy is to stain it with a dye, so that this image is formed by varying thicknesses of gelatine. It is advisable to harden the negative in formaline first, as to make it stand the hot water. If, instead of using carbon film on paper, a sheet of glass coated with gelatine and saturated with the sensitising solution is squeezed into contact with a bromide print, the gelatine will be rendered insoluble, and can then be inked up with collotype ink and printed from as usual in a press. The advantage of this process is that the original print can be re-developed and used for making other collotype plates without the intervention of light, nor is it necessary to reverse the negatives.

#### Curious Water Reflections.

Everyone is familiar with the effect produced in a photograph taken against the sun and over the sea when the surface is rather low down. The result is a kind of lane of dazzling white specks, extending from the foreground to the horizon, and if these specks are closely examined with a magnifying glass, very varied effects can be observed. If we look upon the specks as images of the sun reflected from various water facets existing among the ripples, numerous problems present themselves, and are well worth study. In a great number of cases the specks are rhomboidal in shape, and this is the form that we have generally noticed, and usually expect to see. Within the last few days, however, we have seen some photographs in which the specks are quite a different nature. In the mid-distance they are circles with interior caustics. In other words, they more distinctly show astigmatic coma. In the foreground a very exaggerated kind of astigmatic coma is produced, the caustics develop long wings, and the effect is very much that of a number of white collar-studs floating on the water. The first suggestion will probably be that the astigmatism must be caused by the lens, but this happens to be a well corrected anastigmat that under ordinary tests will show anything like the amount of astigmatism obvious in the specks. Moreover, other photographs showing rhomboidal specks without any astigmatic effects have been produced with ordinary rectilinears capable of giving a large amount of astigmatism. The inference is that the lens has nothing, or practically nothing, to do with the matter, so that the solution of the problem is to be found in the formation of the water facets.

\* \* \*

#### An Interesting Speculation.

This suggests that in the study of the formation of water ripples and facets, we can learn a good deal with regard to the formation of water ripples and facets. Without photography they cannot well be examined at all, so possibly there is a new field of research open to photographers. It is, however, equally possible that someone has already exhausted the field, but we are not aware of any work done on these lines. The astigmatic effects admit of fairly easy explanation if we make the assumption that the water facets are convex and so form little convex mirrors; but if this explanation is the true one, then it would appear that the water formation must have been unusual, for the rhomboidal specks, which are so much more common, cannot be explained in the same way. They suggest the existence of either plane or concave facets of a rhomboidal

pe. Up till now we have not given much attention to subject, as we have generally assumed that specks of a more or less rhomboidal form were always to be found. The perfectly formed little aberration images with sharply defined caustics are quite new to us, hence it is likely that other forms exist that we have never noticed. If any readers have negatives showing such aberrations, we shall be very glad if they will kindly let us have prints for examination. We shall then be able later to report on the effects observed. It is unsafe to speculate on a few results alone, for safety lies only in a multitude of observations.

\* \* \*

#### Parallax.

In a recent patent specification concerning a camera for three-colour work, in which camera three lenses are arranged in triangular fashion, the following curious statement is made: "Owing to the law of parallax a camera with its three lenses is always in focus—that is to say, no focussing is required, as the camera can only be used for objects situated beyond a definite point, varying with the focal length of the lenses used." At first this is unintelligible, but possibly the writer's intention was better than his mode of expression. The term parallax is, however, so frequently misused that we feel obliged in pointing out definitely that there is no "law of parallax" that will serve to keep a camera in focus. Parallax, properly so-called, is an expression defining the difference in the apparent position of an object caused by changing the point of observation, and any such difference is described as a parallactic difference. Thus parallax has a part in vision, for the apparent position of an object varies according as we look at it with the right eye or the left. It also comes in in stereoscopy, for there is of necessity a parallactic difference between a pair of stereoscopic views. Therefore there are also parallactic differences between the three images produced by a triple lens camera used for three-colour work, for which reason such cameras are generally in disfavour. It is obvious that if the differences are considerable the three images will not agree sufficiently to permit their being bound up or ordered in register. They will not register any better than a pair of stereoscopic images produced in similar conditions, and, in fact, two of the images may be used to make a stereoscopic slide.

\* \* \*

#### Distance of Parallax.

There is, however, a saving clause on which the patentee is evidently relying. You cannot produce a pair of images giving stereoscopic relief if the object is distant and the lenses close together. There will be insufficient parallax to show any obvious difference, and to gain enough parallax for stereoscopic purposes you must either increase the separation of the lenses or go much nearer the object. Therefore, you put the three lenses of a three-colour camera very close together and keep well away from the object, one can avoid any unfortunate stereoscopic differences and obtain three images that will register with very approximate accuracy. If, however, any near foreground objects intervene these will not register, and the defects of arrangement will become manifest. It is, then, fairly evident that what the author of the specification meant something like this: Owing to the effects of parallax a camera can only be used for objects situated beyond a definite point varying with the focal length of the lenses. It does not follow that parallax will not exist; it is only necessary that it should be reduced to such a small amount as to be imperceptible.

#### SOME BACKGROUND MATTERS.

It is often a matter of surprise that many portrait photographers make so little variation in their backgrounds. The remark does not apply very much more to the middle-class men than it does to those of the higher class. It must, however, be admitted that well-painted backgrounds are, of course, somewhat expensive, and when one has a stock say of from six to a dozen, even in a good business it cannot be afforded to replace them very frequently. Our immediate object, however, is not to call attention to the frequency with which one may observe a background of some peculiarly aggressive outdoor scene appearing in a photographer's window, but to make one or two remarks on the employment of the plain or graded background which we are glad to see is largely replacing those of the scenic variety in the great majority of studios. There is the idea, we fear, among the less experienced of photographers that they have only got to assume the use of the shaded type of background, and forthwith their work becomes comparable with that of So-and-So, who has made such a reputation for himself by discarding all kinds of rural and marine scenery behind his sitters. Yet it is a fact that the misuse of the plain or graded background is almost as generally evident as the atrocious anachronisms which have been perpetrated with the assistance of the background of the curtain, pillar, and vase type. And, indeed, the portrait photographer ought to see at once that a fixed gradation in the pigment of the background does, indeed, expose him to dangers which he is free from in the case of a perfectly plain background, and our suggestion is that the effects of light and shade should be studied by the aid of a ground of this character, and a further step then taken when a better understanding has been arrived at as to how the grading of the background will assist the natural action of the studio lighting. If, for example, a full-sized background be placed a good distance behind the sitter, and at an angle towards the light, one portion of it will be more strongly lighted than the other, and consequently will be lighter in the picture. The top corner can, naturally, be shaded with the roof blinds or curtains. In this way a graduated background is obtained that will be in unison with the lighting of the sitter. Again, by reason of its great distance from the sitter, considerable atmosphere is secured in the picture, and, conversely, if the background is sloped away from the light, the shading will be reversed. All this is quite easy, yet too many neglect this method and employ permanently shaded backgrounds, and too frequently in such a way that they do not harmonise with the lighting of the sitters.

We have been assuming, in what we have just said, that full size backgrounds are employed; but in the case of bust portraits and vignettes, smaller ones, and with clouded effects, are frequently used, and are of some advantage since, in the case of vignettes, they save the printer some trouble; but, as a rule, there is a great monotony in them, as there must be when only one or two stock backgrounds are possessed. For bust portraits or vignettes only small backgrounds are necessary—6 ft. by 4 ft. 6 in. is ample—and we would advise the photographer to prepare a background suited to the sitter in shape and other respects. A material is to be had of any length up to about 5 ft. wide, under the name of carpet paper, at any of the large furnishing warehouses, at some 3d. or 4d. a yard, and a couple of yards is sufficient for one of these backgrounds. The paper may be had in two colours—one about that of ordinary brown paper, and the other of a lightish grey. Both are useful for our present purpose—the former for bust portraits, and the latter for vignettes.

If we have one or two light wooden frames made, sav

6ft. by 4½ft., with a couple of cross pieces at the bottom as feet for them to stand upon, we can readily make a variety of paper backgrounds suitable for any subject. Each frame, of course, will do for two backgrounds, and it goes without saying that each side of the paper can be utilised. The latter can be fastened on the frames with a few drawing pins, and so can be quickly removed and replaced by others when required. The raw material being so inexpensive, a special shading might even be done for each sitter to suit the colour of the dress of the sitter, whether it be light or dark, and generally to the advantage of the portrait. The carpet papers have a certain amount of tooth, and will retain fairly well any colour that may be rubbed upon them.

For the colours, those sold at the oilshops in powder answer every purpose, and are of quite a nominal price. Those which will be most useful are drop black, burnt umber, and burnt sienna, and common whiting. With an admixture of these a great variety of tints can be made, which can be kept in stock for use when required. They are applied by simply rubbing them on the paper, dry, with a duster or piece of rag. In this way it is very easy, after the sitter is seated, to modify the background by applying a little lighter, or darker, colour, whenever an improvement can be effected, as it is only the work of but a few seconds.

Here we have been dealing with shaded or clouded effects, such as are usually introduced in vignetted pictures. These, however, are not so much in demand as plain bust or half length portraits. But extemporary backgrounds can be easily made by similar simple means to greatly enhance these pictures. Most of us are familiar with the famous Richmond drawings, or Richmond heads. The beauty of these portraits was due in great measure to

the backgrounds, which consisted of hatched, or cross-hatched, lines—light near the face, and more or less bold and strong round the figures. Practically these pictures were vignettes. With these paper backgrounds as described, it is quite an easy matter for anyone to put on some hatched lines similar to those seen in the Richmond pictures. For the bolder ones a stick of charcoal is all that is required. For the less bold, dark brown dark grey common chalks, such as those used by "pavement artists," are very suitable. After the work has been done the effect can be softened anywhere if shading is desired with a duster or a finger, after the manner of the pavement artist, who may be named as an illustration of the rough work that is required. Although it is mentioned how softening of the lines can be done, it is not desirable that they should be softened at all, or only very slightly. The peculiarity of the Richmond backgrounds is that it is all hatching and cross-hatching, fine and open in the lighter portions, and crossed and crossed in the darker parts, especially towards the lower portion of the picture. It goes without saying that the work can be quickly modified when the subject is seated before the background, an operation which will probably impress the sitter with the care which the photographer is taking to obtain a good picture.

The object of these notes, we would again say, is to point out that many portraits may be greatly improved by more attention being paid to the backgrounds, more particularly those of the head and bust type. If a plain background be only slightly relieved with something in the shape of the hatching and cross-hatching of the Richmond heads, the portraits will be far more artistic, and more satisfactory to the sitter, while the reputation of the photographer will probably be enhanced at the same time.

## VIEW-ANGLE AND FOCAL LENGTH IN PICTORIAL WORK.

An editorial statement in THE BRITISH JOURNAL of July 26 gave me great pleasure; for the statement was made "Ex Cathedra," and is therefore beyond all question and criticism:

"From the pictorial point of view, the ideal focal length for use with quarter-plates is 10 in."

It is true that this dogma is immediately qualified, and a short focus lens advocated for hand-camera work; but this short focus lens is recommended on the distinct understanding that only a portion of the film is to be used in the subsequent enlargement, thus maintaining the pictorial narrow view-angle.

Well, as far as the pictorial drawing in the photograph goes, it does not matter whether a 10-in. lens be employed on a quarter-plate, or a 5-in. lens be used on a portion of the film measuring 2 in. by 1½ in., and afterwards enlarged two diameters; for the view-angle of the two pictures will be identical, and provided the photographers stand at the same station point, the perspective in the pictures will also be identical.

### A Pictorial View-Angle.

With the exception of those who photograph for scientific purposes, I fancy every photographer, whether he be professional or amateur, portrait taker or view maker, aims at pictorial effect, desiring to obtain a pretty picture; but of these very few appear to realise the importance of the view-angle.

The view-angle included when using a 10-in. lens on a quarter-plate is an angle of 23 deg.; and exactly the same view-angle would be included if one were to employ a 5-in. lens on a portion of the film 2½ by 1½ (with the intention of subsequent enlargement), or if a 20-in. lens were used on a whole plate. Of course,

this is not the only pictorial view-angle, for sometimes a wide angle must be employed to include the desired subject, as in architectural work; and sometimes, when the distance is beautiful and important, a narrower view-angle is desirable: but for most landscape work, whether commercial or otherwise, a view-angle of 23 deg. will be found to be quite satisfactory:—

Now if a 5-in. lens and a 10-in. lens were used from the same station point, it would be found that the 5-in. lens included twice as much in the picture as the 10-in. lens included; and also it would be seen that the 5-in. lens drew all objects half the size that the 10-in. lens drew them: but in actual practice the man with the 5-in. lens would not choose the same station point as he who worked with the longer focus lens. In actual practice both these photographers would desire to depict a certain prominent object, such as a cottage, or a group of fishermen, a clump of trees, a certain size in the picture; and therefore the man with the 5-in. lens would choose a station point nearer the principal object. Consequently, although each photographer would draw the cottage the same size, the user of the 5-in. lens would depict the distant hills only half the size of those in his comrade's picture.

This is more important than it may appear at first sight, for it is the principal object of interest which sets the scale of the picture that is depicted in the rest of the picture; and if the distance be drawn too small, it will appear dwarfed and insignificant, and give an impression that it is smaller and farther away than it is in reality. It is easy to test this fact by examining the photographs of known places in a railway carriage or view

m: in nearly every case, provided these photographs be  
ained calmly and critically, it will be found that they con-  
an entirely false impression of the places which they are  
aded to depict; the lofty cliffs of Newquay appear low and  
t, the noble mountains of Scotland and Wales insignificant  
uninteresting; lakes and bays appear too wide and empty.  
only where the scenery is crowded and confined that the  
r view-angle is an advantage, since it makes the more distant  
ts appear further off and less overwhelming; but even here  
se impression is given, and the place which looks so beauti-  
in the photograph will prove disappointing when viewed in  
ty.

### Long-Focus Lenses.

suming that a view-angle of about 23 deg. is desirable in  
ictorial work, the question before us is this: shall we  
oy a 10-in. lens in our quarter-plate camera, or use a  
mary 5 in. lens and enlarge a portion of the film?

every practical photographer knows, the employment of a  
long focus lens in an ordinary hand-camera is impractic-  
owing to the difficulty of securing the object of interest  
ne sharpest possible focus, and also because the foreground  
distance are apt to come too much out of focus. But at the  
of questioning an "ex cathedra" decision, and incurring  
major excommunication, I venture to suggest that a 10-in.  
in a reflex camera is quite within the realms of practice,  
that the two form a happy combination.

ter some five years' experience of reflex cameras fitted with  
lenses, I ought to know the subject from a practical stand-  
t; and I can say that I have found the theoretical objection  
such lenses lack sufficient depth of focus at the larger  
ures to be purely theoretical. Of course, those who wish  
photograph a group of fishermen in sharp focus, and at the  
time render each rope in the rigging of the distant fishing  
ks equally distant, would find a 10-in. lens at  $f/8$  unsatis-  
f; but anyone who seeks that aerial perspective which  
tained by softening the distance and blending the details  
e distance into soft masses of light and shade will find a  
focus lens an unmixed blessing.

ind, I am not speaking of fuzzy work, for no one desires  
ness and cleanness in the original quarter-plate negative  
than I do; but I desire the same quality in my photo-  
hs that I find in all I see, for when I look at some object  
ature and focus it clearly with my eyes, I find that my  
n blends the more distant objects into broad masses of half-  
s so that they may not disturb me, nor distract my atten-  
from the object at which I am gazing.

actual use, I find that when the principal object is some  
nce from the camera, so that a horse would give an image  
t half an inch high, a 10-inch lens can be used at  $f/5$ , with-  
making the distance too fuzzy; and the sharp foreground  
ng against a softened distance stands out clear and distinct,  
st the softened distance goes back into its proper plane.

quality is lost when a 5-in. lens is employed.  
ith larger figures in the foreground, it is usually desirable  
top down to  $f/7$ , but the longer I use these long focus  
s and the more experience I acquire, the less need do  
d of stopping down.

hen as to the objection that it is sometimes difficult to get  
enough away from the object to be photographed—and in  
ing this I am simply tempting the powers to hurl anathemas  
excommunication at my head—it may be difficult at times,  
it is worth the trouble it involves. Take any group of  
rmen or peasant women with a 5-in. lens, and you have a  
p of wooden figures, with sheepish grins and empty heads—

even children seldom stand the ordeal; take them with a 10-in.  
lens, and, as you wait your time, pretending to focus and so on,  
you will find their faces grow natural, their muscles relax, and  
their poses become natural.

The chief objection to a long focus lens is the bulk of it, and  
the weight of it, and the cost of it; and I acknowledge that this  
is a very practical objection. Probably, if I were to buy a new  
lens, I should follow the advice I gave a friend, and sacrifice  
some of the aperture, and an inch of the focal length, and buy  
a little 9-in. lens working at  $f/7.7$ .

### Short-Focus Lenses.

I have nothing to urge against short focus lenses, as long as  
the editorial counsel is followed, and the view-angle is kept  
narrow by only enlarging a portion of the film. But perhaps I  
may be allowed to offer a few suggestions founded on personal  
experience.

If the ordinary hand-camera be employed, and the image be  
sought and the picture arranged in the tiny finder supplied with  
the camera, it is generally useless to think of enlarging only a  
portion of the film afterwards; for not one in a thousand, with  
that dainty little image before him, will be able to mentally  
pick out a portion of that image to form his picture. Again,  
if the picture be arranged on the focussing screen of a camera  
fitted with a short focus lens, the camera will instinctively be  
brought near enough to the principal object to make it appear  
large and important on the focussing screen; and when a por-  
tion of the negative is enlarged it will be found that the ultimate  
size of this principal object is simply overwhelming. No, if  
either the finder or the screen be employed in the composition  
of the picture, in most cases the whole of the negative must be  
enlarged if the result is to be satisfactory.

If the advice given in the editorial columns is to be followed,  
the man with the ordinary quarter-plate camera, who proposes  
to enlarge a small portion of the film, will find three courses  
open to him. He must either have a new finder which includes  
a narrow view-angle fitted to his camera; or he must mask the  
edges of his focussing screen, and compose his picture on the  
remaining space near the centre; or he must use some view  
finder, which is quite separate from the camera, for the purpose  
of selecting and arranging his picture, and only employ the  
finder on the camera for the purpose of centring his subject.

I have never tried the first course, as I find the brilliant  
little picture in the bright finder somewhat deceptive and mis-  
leading; but I have found the masking of the edges of the  
focussing screen, so that an oblong aperture measuring 2 by  
 $1\frac{1}{2}$  in. is left in the middle, excellent; if a small square readin-  
glass be employed to focus with, a very good idea of the effect  
of the picture, when it has been enlarged, may be obtained.

The third alternative is perhaps the most satisfactory: a  
sheet of stout cardboard measuring 6 by 5 in. is obtained, and  
an oblong aperture 3 by  $2\frac{1}{4}$  in. is cut in the centre, so that the  
remaining card forms a wide frame; a piece of string is attached  
to the inside edge of the frame, and a knot tied at a distance  
of  $7\frac{1}{2}$  in. from the card. In practice the frame is held parallel  
to the face, and the knot placed against the cheek-bone to give  
the distance. By raising the frame slightly the effect of a rising  
front may be ascertained. The photographer must not forget  
to stoop down to the height at which he will hold his camera.

Whatever method may be adopted, there is no doubt that in  
most cases the ideal view-angle for pictorial work is similar to  
that which is included when a 10-in. lens is used on a quarter-  
plate.

A. J. ANDERSON.

at the Ashby Police Court last week Frederick W. C. Page,  
tribed as a photographer, of no fixed address, was charged with  
ing six bagatelle balls, value 21s., the property of Geo. Barnett,

licensed victualler, Measham, on April 25 last. The Chairman said  
there were twenty-six previous convictions against the prisoner, who  
would be sentenced to three months' hard labour.

# THE COMPOSITION AND PROPERTIES OF THE SALTS FORMED IN THE FIXATION OF BROMIDE AND CHLORIDE PLATES.

In our previous studies on the use of the fixing-bath we have shown that the quantity of silver bromide dissolved by a given weight of sodium thiosulphate (hypo) does not correspond with any of the recognised formulæ for the salts supposed to be formed. It is assumed that the silver halides dissolve in hypo with the formation of the same double salts as are formed when silver nitrate and hypo are used. The salts formed differ according to whether one uses an excess of, or insufficient, hypo. In the first case it is assumed that there is a combination of three molecules of thiosulphate and two molecules of halide, according to the equation:—

In the second case that the two salts combine in equimolecular proportions according to the equation:—

We have tested the salts formed in fixing plates and paper to see whether they actually have the composition supposed.

## Silver Bromide.

If in the dark 15 and 45 per cent. solutions of hypo are saturated with freshly precipitated and washed silver bromide, 63 grammes of silver bromide are required for 1 litre of 15 per cent. hypo solution, whilst the quantities calculated for the following formulæ are:—

In the case of a 45 per cent. solution of hypo the quantity of silver bromide is 205 grammes per litre—that is, about three times as much as with the 15 per cent. solution.

The solutions thus obtained were filtered, and the undissolved residue analysed after the soluble salts had been removed by repeated washing. This residue was found to be pure silver bromide, the excess of the silver halide which was added to the hypo. This result is opposed to the accepted hypothesis of the formation of the salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . As this salt is but slightly soluble in water, it should have been found mixed with the excess of silver bromide. Further, the solution when filtered remains clear: no insoluble salt is deposited. We tried to isolate the double salts contained in this solution, first by fractional evaporation at low temperatures, and also by the addition of an equal volume of alcohol. In the first case small quantities of silver sulphide were thrown out of solution, and could be removed by filtration as they were formed. When the solution was sufficiently concentrated, the pearly-white scales which were deposited were collected by drawing off the mother liquor, washed with a very small quantity of water, freed from moisture on a plaster tile, and dried at 105 deg. Fahr.

If the mother liquor is evaporated, a second, and even a third, quantity of crystals can be obtained, having the same appearance as the first.

Instead of evaporating the solution, it can be mixed with an equal volume of alcohol. There is then obtained an oily separation, which collects at the bottom of the liquid and soon sets to a crystalline mass.

The separation of this oily liquid can be avoided and well-defined crystals obtained, if the solution is first mixed with sufficient alcohol to form a permanent cloudiness and a few crystals of the substance then thrown in. On violently shaking and adding more alcohol to complete the precipitation and allowing to stand for some hours, a fine crop of crystals will result.

The crystals thus obtained should be collected, drained,

washed with alcohol, dried on a plaster tile, and then finally in a drying chamber at 140 deg. Fahr. The product, as well as that obtained by fractional evaporation, was analysed, and the sulphur, soda, and silver therein estimated. For this purpose it was heated in closed tubes at 446 deg. Fahr., with concentrated nitric acid, so that the silver was converted into nitrate and the sulphur into sulphuric acid. The products were then evaporated after adding hydrochloric acid, so that the nitric acid escaped and the silver precipitated as silver chloride, and weighed. The sulphuric acid was estimated as barium sulphate and the soda as sodium sulphate.

The following is the percentage result of this analysis:—

	Fractional evaporation of 15 per cent. to 40 per cent. hypo solution saturated with silver bromide.			Precipitation of the saturated solutions with alcohol.	Results calculated for—	
	1st Fraction.	2nd Fraction.	3rd Fraction.		$\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}.$	$\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}.$
Sulphur.....	28.5	28.2	28.2	28.3	25.99	28.2
Silver .....	31.7	31.8	32	31.6	42.85	31.76
Sodium .....	19.6	13.4	13.4	13.5	9.12	13.53
Water of crystallisation .....	5.3	5.3	5.3	5.3	8.5	5.3

These results show that, in spite of the excess of silver bromide, only the salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , which is very soluble in water, is formed, and that the salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$  not formed, as is usually assumed.

This salt appears as white pearly glistening scales, of very sweet taste, which are very soluble in water (about 60 per cent. at 60 deg. Fahr.). The solution diluted to 1 : 1,000 is slowly decomposed with the formation of very finely divided silver sulphide, which makes the solution brown without any precipitation.

The concentrated solutions up to 5 per cent. are stable, and can be heated to 212 deg. Fahr. without silver sulphide separating out. Yet this decomposition takes place if the solution is boiled for a long time, and in the light the solutions slowly deposit silver sulphide.

Above 5 per cent. the solutions deposit—with increasing rapidity and quantity the more concentrated they are—well formed transparent crystals, which are insoluble in water. These were analysed after being freed from every trace of mother liquor by repeated washing. As nitric acid only slightly attacks them, the analysis was made with bromine water.

The following were the results:—

	Calculated for $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}.$			
	...	...	...	...
Sulphur ...	25.37	...	...	25.39
Silver ...	42.78	...	...	42.85
Sodium ...	9.10	...	...	9.12
Water of crystallisation 3.56	...	...	...	3.5

This compound, insoluble in water, has then the composition of the double salt, which has hitherto always been assumed to be formed by the action of silver nitrate on an insufficient quantity of sodium thiosulphate. It also possesses the properties which have been ascribed to this substance, its characteristic insolubility in water, its instability in heat. It blackens at 104 deg. Fahr. with the formation of silver sulphide. This substance appears, therefore, to be formed by the action of water

the salt, which contains 2 molecules of sodium thiosulphate and 1 molecule of silver thiosulphate.\* This does not appear to be formed when a 15 per cent. solution of hypo is saturated with silver bromide, for one litre of this solution only requires 63 grammes, and not 76, which would correspond to the salt in question.

The solution obtained appears from the calculation to correspond to a double salt which is formed by the action of 5 molecules of silver bromide on 9 molecules of thiosulphate. This compound is without doubt unstable and exists only in solution, as it is only possible to isolate the salt corresponding to the action of 2 molecules of silver bromide on 3 molecules of thiosulphate.

#### Silver Chloride.

We have ascertained that when a 15 per cent. solution of hypo is saturated with precipitated silver chloride in the dark, it can (contrary to when the bromide is used) dissolve exactly the quantity which corresponds to the formation of the salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3$ —that is, 58 grammes of silver chloride for 150 grammes of crystallised thiosulphate.

If the solution with the excess of silver chloride be filtered, the silver is deposited gradually in the course of time considerable quantities of a compound in large transparent, very regular crystals, which are insoluble in water and possess properties very similar to those assumed for the double salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$ .

The analysis of this substance, after repeated washing with water to remove every trace of the mother liquor, gave the following results:—

	Found.	Calculated for $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ .
Silver	24.36	24.6
Sulphur	40.99	41.1
Sodium	8.75	8.81
Water of crystallisation	6.7	6.9

This compound, therefore, contains one molecule more water than the double salt formed when silver bromide is used. If an aqueous solution is precipitated with alcohol, as described for the bromide, there is a separation of white plates which are a mixture of two substances.

The substance is not completely soluble in water, and there remains considerable crystalline residue. The analysis of this residue gave:—

	I.	II.	III.
Sulphur	32.3	31.6	—
Silver	38.3	37.7	39.7
Sodium	10.7	—	—

It will be seen that the composition is not constant, and is

This decomposition partly takes place when one tries to purify this salt by dissolving it in water and precipitating with alcohol. A compound is then obtained in white scales, which are only partly soluble in water, and which is probably a mixture of the two double salts of the following composition:— $\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O} \cdot 2\text{Na}_2\text{S}_2\text{O}_3$ ,  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ .

intermediate between the two compounds isolated when silver bromide was used. Alcohol precipitates, in the case of silver chloride, a mixture in variable proportions of the salt which is formed of 2 molecules of thiosulphate and 1 molecule of silver thiosulphate and that formed of equal molecules of the two thiosulphates.

If the insoluble part of this mixture is separated by filtration and purified by repeated washing, a body is obtained in small transparent crystals, which from its composition and properties may be considered as  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ .

The same substance is also obtained if the mother liquor from which these crystals are obtained is tested. The properties of this solution coincide with those of a solution of the double salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ . This double salt could be isolated in a pure state. If one tries to precipitate it from an aqueous solution, or to obtain it by evaporation, there is always obtained a compound only partly soluble in water, and the insoluble  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is found in the residue.

#### Summary and Practical Conclusions.

It appears from the foregoing that the solution of silver bromide and chloride in thiosulphate does not give the same double salts. These compounds are, indeed, in both cases double thiosulphates of silver and sodium, but their composition is very different from that which has hitherto been supposed. They appear to be the same whether a 15 per cent. or a 45 per cent. solution of hypo be used.

In the case of silver bromide it may be assumed that the saturated solution contains a double salt composed of 5 molecules of silver bromide and 9 molecules of thiosulphate. This salt, which only exists in solution, precipitates on evaporation or precipitation with alcohol a double salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , which, in sufficiently concentrated solutions, is gradually decomposed into the double salt  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , which is insoluble in water.

In the case of silver chloride the hypo solution is saturated with a quantity of silver halide which exactly corresponds to the composition of  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , but the saturated solution deposits an insoluble salt of the formula  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ . Finally, from this solution there can be isolated the two double salts, which can be separated in the case of bromide.

Although these results lead to a conclusion differing from that which has hitherto been assumed, they nevertheless confirm the danger of using the fixing bath till saturated with silver salts. There is danger of the formation of insoluble and unstable double salts, which may be formed directly with the silver chloride deposited on the image so that it cannot be removed, or indirectly and deposited generally in the film.

It is important, therefore, in fixing plates and papers to avoid using the fixing solution until it is saturated with the silver halides.

A. AND L. LUMIERE.  
A. SEYEWETZ.

## KEEPING TABS ON YOUR BUSINESS.

[Causes of leakage of business and expedients for improving things are strong points with the American photographers, but not all of them can write about the particular ways and means as does Mr. Pirie MacDonald, of New York, who, in the "Photographer," has been telling his colleagues exactly how he keeps his clients warm to the task of making up their minds as to proofs which at first may not immediately please them. Mr. MacDonald's method, as described in the following article, is, after all, an application of the card index.—Eds. "B.J."]

Twelve years ago a man stopped me on the street and said that he would be glad to pay his account if I would send him a bill. That night, during the long black watches, when business becomes a nightmare, I dug up another case of a man whose money I did not remember getting, but whose pictures had been delivered.

When I searched the books the following day no trace of a charge could be found, and immediately thereafter was developed a most desperate case of "blue funk."

In those days suspicion used to take on violent form much more easily than it does now—probably because I knew less, and thought I knew more, than I know that I know now. At any

rate, I got busy in an effort to stop the leak that looked as though it spelled "Ruin," and to try to get all that was "a-comin' to me."

On thinking the matter over very carefully I found that there was another fault that should be overcome at the same time—that, after making a set of proofs, and because the sitter forgot about them, or was only partly interested, or the proofs were not sufficiently satisfactory, the order was never booked. I found that it was only spasmodically that we looked the matter up, and that the spasms were infrequent and irregular, and that many times the proofs had been sent so long before we discovered it that it seemed like impudence to attempt to revive interest in the affair, and much more to force an issue.

About that time the card systems were first being exploited, so it was natural to turn to cards for the solution of the "charging" difficulty—to make out a card every time a sitting was booked—to put it with all the other orders until the work was delivered—then to mark it "Charged" when the charge was made, and then—and not until then—to put away the card. It would be a reminder every time it was handled, and as it, with the others, would be looked over every day, the delivery without charging would be discovered within twenty-four hours; and, as the card would be taken out of the set when charged, only live matter would be handled. Not like the register, where it would be buried with a lot of "proof out," "in work," and "delivered," but only with live accounts.

As a similar arrangement would have to be made to keep track of "proofs out," it seemed as though the office work would increase in volume tremendously—though the results attained would each warrant the extra work, it was necessary to keep the labour item down in order to make the most money, so we devised a card which would get rid of the necessity for a register, and be at once a register, a record of "proof out," and a sure check on "uncharged deliveries"—and here it is:—

#### THE RECORD CARD.

No. ....	Name .....	Date .....
Address .....		
Order .....	\$ .....	
.....		
.....		
Finished .....	Total .....	
Delivered .....	Cash Cr. ....	
.....		Balance .....
.....		
.....		

You will notice the usual space for negative number, date, name and address, order, price, total, cash credit (deposit), date of order, date finished, date of delivery, and the space for rubber stamp to denote "paid" or "charged"—in fact, everything that the register gives.

The way to work it is this: When a sitting is made the card is filled out with the name, address, and date—some folks fill the order in at the same time—we do not, for we always hope that they may be induced to eventually believe that they want more than they think they want when they sit—and we always stand open to an endeavour in guiding them toward that belief.

When the card is filled out put it in a pigeon-hole in the desk marked "proofs" (see diagram), and there the card stays until the proofs are sent out—though honesty impels me to state that proofs are sent out as rarely as possible, for we feel that a little chat in the studio enables us to assist materially in selecting the best proofs, and prevents the customer overlooking certain proofs that they otherwise might not have noticed! However, when the proofs are sent out the card is placed in the next compartment "proofs out" (see diagram).

This is the little hole that has the prize—this is where you make money out of what would otherwise be of the scrap heap. When a man or woman has had a sitting they have proved that

they have some interest in photographs—it should be easy to sell to one who is already started—then why advertise to people who have no interest in pictures when the labour and money can be used on people who have already told you that they want pictures—people who know you—who have been in your place and who know just what you are doing—who know your prices and styles—and have had confidence enough in you to come to your studio?

Sure enough, it is easier to get them to buy than to educate a stranger—cheaper to make a resitting than to make a brand new customer—and remember that people leave your shop either as "boosters" or "knockers"—if they do not just exactly like the proofs—even though it is their own fault, it is better for you to spend a little more on them—sell the full order and make "boosters" out of them.

Use up what you have on hand before you cut into new material. Many photographers cry about lack of business, where, if they would finish up what they have started they would be busy at all times—more profitably—and with more satisfaction to themselves and their customers—for your customers respect a man who is "on the job."

I loathe waste, and when a person has gone so far as to have a sitting and you fail to satisfy, and sell to them, it is waste!

Nearly everybody asks, "But how do you get them in again? what do you write to them?" Though this page is not a "Photographers' Ready Letter Writer and Compendium of Polite Correspondence," I will give you an outline of how to do it. At the end of the first week we write to the effect that "We imagine that they must have been busy, as the proofs have not been returned, and we know that they are in a hurry for the pictures—we let us know what they want and we will use all expeditiousness and will not let their delay affect the delivery." Then three days later we write that, "As they have not yet found time to come in with the proofs we will be glad to send someone to them about their order if they will appoint a time." This usually brings a response, but if it should not, within a week a letter is sent saying that we are beginning to fear that the proofs are not wholly satisfactory or the order would have been placed—and though two or three of the proofs are splendid pieces of workmanship, we realise that expression is a matter of individual fancy—and if it is not just what they want we will be glad to make another sitting—won't they come and tell us about it, etc.

In nine cases out of ten this third letter will bring them again—and gives us the chance we want—for with the proof before us we can readily make such changes in a new sitting as will satisfy the customer. Of course, that is what we want to do—really please the sitter—it is not so hard to do when you know what they want—and pictures can be sold when they really please.

the third letter does not do the work at once, someone is to see the party, and the matter is closed one way or another. If a small order is accepted from the most satisfactory customer, or an appointment for a resitting is made, or the whole is closed—to the satisfaction of the sitter. Better be generous enough to mark the card "no order" than let the letter drag. Clean things up as you go along—it makes you better and you know where you stand—and all this within a few weeks—you keep them warm all the time, with no chance of cooling off.

Just write up your last month's business and work the details through on this plan, and see whether it does not help for the trouble.

After the order is placed, fill out the card as you would in a register and place it in the "order" compartment (see diagram), and there it stays until the pictures are delivered. When charge is made or the money is paid the card is filed in the filing cabinet.

Think of the command you have over your business while

you are sitting at your desk with the orders all in one pigeon-hole in front of you—only the live orders. If the package is too large, the shop is not working up to the business, and needs pushing. If the bunch is too small the sales are running behind, and more hustle must be made for new business. The "proofs out" need crowding. If you watch the size of the package you will always find it too large or too small—something always needs pushing, and what we Americans like is to know what to push—we have plenty of it, but it is hard to tell just what is the right thing to hammer—and the "order" cards are a sure and constant indication—it tells you every day, either "push in" business or "push out" work.

It is all so simple and easily done that anyone can do it, and the scheme has the great advantage of putting to one side everything that is finished and keeping on hand only the cards that tell of the work in hand—you do not have to look over endless and confusing columns to find out about an order, for you have only as many cards as you have orders unfinished.

PIRIE MACDONALD.

## WATER-COLOURING OF PHOTOGRAPHS.

The following article, which we quote from the "American Amateur Photographer," in continuation of that which appeared in the "B.J." March 29, 1907, affords instruction in the use of water-colours for the chromatic finishing of photographic prints. The previous article is the same author dealt with wash-colouring with aniline dyes.—Eds. "B.J."]

In the previous article it was my purpose to present a colouring method by which anyone unfamiliar with painting as an art could use the various mineral colours now upon the market and produce good results. Briefly stated, this class of colouring is known as "wash painting," and while it is true that the majority of the so-called hand-coloured photographs are wash-painted, because it is easier and requires less skill, still it has remained for the true artist to produce something finer, a picture that will give him credit for his knowledge as to the proper uses of water colours and the methods employed in their application. Knowing that one's artistic tastes are apt to have led him into the two channels of artistic expression, water-colours and photography, it is my purpose in the following article to show how the combination of them is capable of producing results of great artistic merit. It is therefore to the photographer who knows something of water-colour painting in the ordinary acceptance of the term that I speak.

### Taking the Photograph.

If you intend to produce really artistic and well-appearing coloured prints you must begin with that idea at the very start of the picture-taking process—namely, the plate and its exposure. I take for granted you well understand the fundamental rules of composition, proper exposure, development, etc., and I will only add a few hints regarding these special stages of the work.

1	2	3	4	5	6
7					

Subject	New Jersey Farm
Exposure $\frac{1}{2}$ sec.	Stop f-8
Tree trunks	- 5-6
Tree foliage	- 2-3-10
Fallen leaves	- 4-2-3
House	- 5
Roof	- 13
Sky tints	- 6 (light) 5
etc., etc.	

Select a subject that you think will colour well, some quiet little woodland bit, for an example, with soft, pretty foliage, and marked variations of colour. An orthochromatic plate for this purpose will be found the most satisfactory. Stop down the diaphragm and lengthen the exposure to ensure good detail. Try, if possible, not

to procure too dark shadows or extreme high-lights, but work for half-tones.

Before packing up your impedimenta and moving to the next place, jot down in a note book provided for the purpose the colour of the principal objects in your picture, such as sky tints, etc. If you wish to be more exacting in regard to procuring as nearly as possible the original colours of the subject, the following method will be found extremely helpful, and which the accompanying diagram serves to illustrate.

Let No. 1 and No. 2 be two leaves of your note-book, the first being the "Colour Reference," the second a separate memorandum for each individual picture. If one understands the mixing of colours the above method may be seen at a glance to facilitate long and cumbersome descriptions.

I advise the use of pyro as a developing agent, as it, without doubt, gives a better negative for platinum printing. Develop for detail and not misty effects.

### Printing.

A fine quality of platinum paper is to be preferred, above all others, for this class of colouring, as the texture of the paper most resembles that used in ordinary water-colour work, and is capable of greater artistic results. A medium rough surface will be found more easy to work upon than a smoother grade.

Print until the shade corresponds in depth to that of an ordinary uncoloured photograph. Many make the mistake of thinking a print should be lighter in tone. After completing this operation and having procured a print which you think will colour well the next things to consider are the

### Necessary Materials.

An ordinary wooden drawing-board, four thumb tacks, a box of good water-colours, a magnifying glass (for painting fine detail), a porcelain compartment palette, and a glass of clear water will complete the equipment. With your print (untrimmed) carefully tacked upon the board (it is a good plan to have a blotter between), you are now ready, with the help of your colour memoranda, to begin

### Applying the Colour.

Before doing this let me caution you to bear in mind the following facts as you work:—

Determine the source of light by the shadows and manipulate your colours accordingly.

Do not make the mistake of preparing thin washes and merely brushing over the different objects in the picture. For certain kinds

of paint this method is all right, but with water-colours you must use the colours in their full strength and apply them with the same amount of skill and dexterity, as if working upon a plain, white piece of paper! The print must act merely as a suggestion as to where the colour shading must go.

Please bear the foregoing paragraph well in mind; *it is the most important of all!*

Do not brush over the same surface more than is absolutely necessary, if you desire your print not to look "mealy."

Keep the mixing water in the glass as clean as possible, thus ensuring brilliancy of colour tones.

Don't hurry matters by trying to get "sketch effects." Sketchy painting, unless done upon a print especially in keeping, is anything but pleasing.

Pay strict attention to distances and try to vary your colour shades so as to render the proper effect of "atmosphere."

With these "don'ts" well in mind, you may now apply your colours. The first thing to be considered in colouring any landscape is the sky. Beginning at the horizon (brushing over all things that rise before it), carefully blend the proper tints. Now work in the picture proper and relieve the too dark shadows with Chinese white. In sunset effects always add a small amount of the predominant sky colour to the strongest of your high lights, thus rendering greater harmony of colour.

There is perhaps nothing that is so valuable to the colourist as Chinese white for giving brilliancy and snap to a picture. In snow scenes it will be found extremely effective if a little is applied here and there, the result being a delicate shimmer. A line or two upon a clear expanse of water will also prove an added touch of beauty to any marine.

### How to Treat Detail.

While it is most essential to devote your best time and care to the working in of fine detail, do not make the mistake of grouping too much together. Two or three small but nicely coloured flowers along a hedge fence are infinitely more pleasing than a mere mass of merable tiny spots or various colours scattered promiscuously over a great area. In short, what detail you do colour, do it well, and do not have it "spotty."

Masses of green appearing in the immediate foreground can be effectively relieved by a few short perpendicular strokes of light green mixed with Chinese white, giving a suggestion of grass blades.

### Mounting.

After a print has been coloured it will quite likely have a tendency to curl. This can easily be overcome by taking a moderately hot sad iron and ironing the print face down until flat. It can then be mounted on a white, plate-marked (embossed) card, merely touching the two upper corners with a strong paste. To ensure the print lying perfectly flat after this operation, place a piece of paper over the print and hold the iron on to the pasted card until dry. With a picture of this sort it is customary to place a title and your written signature, using an ordinary lead pencil, beneath the print, although this is purely a matter of taste.

In conclusion, I can only add that you keep your eyes open for high-class coloured platinum prints, and study carefully as to how colour has been applied. This you will find will help you greatly.

A few photographers, who are also water-colourists, are, in various parts of the country, devoting all their time to this branch of picture making, and, furthermore, are commanding flattering prices for their hand-coloured prints that are difficult to distinguish from genuine water-colours.

JAMES C. SAVER

## FOCUSSING WITH THE "SWING-BACK" AND "SIDE-SWING."

THE following note by Mr. Felix Raymer, in "The Professional and Amateur Photographer," conveys a practical lesson that may be useful to many:—

A special request has been made that I explain, in an article upon that subject, the use and the manner of using the "swings" on a portrait camera. The asking for information on this subject, I am sure, will voice the feelings of many operators, for if there is any one thing about the camera that many do not understand, it is the use of the "swing." Not only are there many who do not know their use, but many who do not know they are on the camera. Yet their use is of the utmost importance at times.

Before going into the question of their use, we must first know what a properly focussed negative looks like. Some think a portrait should be made as "sharp" and clear cut as possible, regardless of portrait effects. Operators, so believing, often discard their very best negatives, thinking they are out of focus. It is a common occurrence to have such an operator say, "I believe in having everything as sharp as possible, for the people will take almost any old thing if it is only sharp and clear cut." To prove this is not true, I will suggest that the operator claiming it makes six negatives of his next sitter, five of them made as sharp as he can, and the remaining one just a trifle out of focus. Show proofs, leaving it entirely to the sitter to select the one preferred, and, in all probability, he will select the one a trifle off the focus, "because it looks so soft and round." I do not wish to be understood by this as an advocate of throwing all of the picture out of focus, for if there is any one thing I do detest it is the ridiculous stuff made by certain faddists that have to be accompanied with a catalogue so one may know what it is. This class of work is even worse than the black smudgy stuff that was foisted upon an unsuspecting public some few years ago, and which was labelled "art" by a few would-be artists. All I can say for that smudgy stuff is the sitter looked like he had just been snatched out of the middle of Hades and had not had time to wash the "smut" off his face.

Whilst I do not believe in throwing all of the portrait out of focus, neither do I believe in throwing it all into focus. If an operator wants his pictures all in focus he can secure that effect by using any ordinary cheap R.R. lens, working at  $f/8$ , and thus not have to

invest from one hundred to two hundred dollars in a portrait lens. The manufacturers of lenses have, through their portrait lenses, shown the operator what a true portrait effect should be when their lenses are assured to do what they are designed to do. Now if the operator will compare the result of such a lens with that of a small R.R. lens, he can see for himself the proper effect.

One often sees pictures at the conventions that are very fine, with the one exception, they are too sharp and "wiry," thus killing one of the greatest essentials in portrait work—atmosphere. Many times an operator admires a piece of work made by another operator, but he tries to produce something like it, but fails for but one reason, and that is a total lack of knowledge of proper atmospheric focussing.

Now to get at it as plainly as possible, we will suppose we are looking our subject squarely in the face. What feature do we really look at? The nearest eye to us is usually the one we look directly into. We know the sitter has two eyes, but we cannot look directly into but one at a time, and that one is usually the one that is nearest to us. Our direct sight takes in a small circle, of about two or three inches diameter. This takes in the nearest eye, and nose; the balance of the face and head we know to be there, but it is taken in "out of the tail of our eye," as we say. Now it is nothing but natural to look at what we are interested in, and when we are talking to a friend we look him in the eye, and not in the mouth, ear, or chin. Therefore, to make our pictures natural we must attract attention to the part or parts that it is natural to look at. To attract attention it must be done by a concentration of light, and then a concentration of focus at that part. Therefore, we have a concentration of focus as well as a concentration of light; the portrait lens being designed to that very end will produce it unless the operator counteracts their natural results into another result by the use of small diaphragms. Now that we have considered the concentration of focus, we will go into the manner of securing it.

We will suppose our sitting to be a "bust," and the shoulders varying distances from the camera. First, focus on the part of the face on which the light has been concentrated, which is the nearest eye to the camera, taking in a bit of the forehead and nose. Make this little circle as sharp as possible, using the regular focussing attachment. Next, look into every other high-light appearing in

ce, and it will show a lessening of sharpness as it shows a lessening of light. This is focussing in harmony with the lighting. Next look the outlines of the entire figure and head. The outline of the head, the farthest from the camera, will be found decidedly out of focus; so will the nearest shoulder to the camera. Now the usual proceeding to bring these two extremes into focus, followed by the operator who does not understand the use of his lens, is to insert "stop" small enough to bring them into focus. Just there he loses the pictorial qualities of his picture by having changed the focalities of his portrait lens to the focalities of a view or group lens. What he should do is to use the "side swing," turning the ground glass at a side angle, until the two extremes come into focus simultaneously, or as near into focus as the side swing will bring them.

Next examine the base of the figure and the drapery generally. It will perhaps be a trifle out of focus. If so, use the "swing back," turning the ground glass at a perpendicular angle until the base comes into focus, after which use the general focussing attachment, again dividing or spreading the focus. If this plan is followed there will be no occasion for using stops on single figures, thus making it possible to shorten the exposure and, at the same time, secure the true portrait effect.

In focussing on groups follow the same plan as outlined for single figures, focussing first on the centre of the group, next using the "side swing" for the two ends, then the swing back for the top and bottom; then divide the focus or distribute it all over the group with the general focussing attachment, and, last of all, the "stops."

## A NEW COLOUR METER.

[The following paper, on an instrument for the numerical measurement of colour, was read by the inventor, Mr. F. E. Ives, before the Franklin Institute of Philadelphia.]

has long been recognised that a universal colour meter, capable of measuring all colours and expressing them in numerical terms, must be based upon the principle of Clerk Maxwell's "colour box," in which half of a divided field is illuminated with ordinary white light, while the other half is illuminated by an adjustable mixture of the three simplest colours of the spectrum, isolated bands of pure red, green, and blue violet.

Without any alteration Maxwell's colour box could be used for measuring the colours of transparent objects, such as coloured glasses and solutions, placed in front of the aperture for direct light, but it is not adapted for the measurement of the colours of opaque objects. It is also necessarily a large and clumsy instrument, that, instead of Maxwell being of elbow form, several feet in length, and that the adjustments for taking measurements of a complicated character and quite out of reach of the observer at the eye slit.

Although many attempts have been made to devise a colour box type colour meter to meet the various requirements in the industries, none of them has proved successful, and manufacturers have found nothing better for their purpose than a "tintometer," which uses merely arbitrary scales, different and distinct sets of which are made for a large number of trade uses.

The new colour meter is a direct vision instrument, the body of which is about 3 x 4 x 20 inches in size, with all the operating adjustments controlled by screws a few inches from the eye. A low dispersion grating is used in place of the prisms in Maxwell's colour box, and the field is so divided as to be illuminated through a central slit for ordinary light on one side, and through three laterally dis-

covered for protection by the thinnest microscope cover glass, and closed by sliding brass plates which are controlled by micrometer screws. Theoretically, the slits should close from both sides towards the middle; but that is a quite unnecessary refinement of adjustment for this instrument. Each micrometer screw head carries a pointer which moves over 100 divisions of a concentric scale to fully close or open the respective slit, thus reading to 1 per cent. The scale numbers are read off when the two halves of the field match in hue and luminosity, and recorded as 50 R, 20 G, 60 B, or whatever it may be, as a numerical expression of the colour of the object.

Should the shape of the coloured object be irregular, the insertion of a thin prism in front of the central slit will displace the image laterally, so that a portion at some distance from the edge of the object will come to the inner edge of the divided field, without invading the colour mixture half of the field. Very small transparent objects, such as bits of coloured glass, solutions in flat glass cells, etc., are placed directly in front of the central slit, and thus made to fill the right field.

The use of a grating in place of prisms in a colour meter is believed to be quite new. By no other means would it be possible to make a compact direct vision instrument with a sharply divided field, in which one-half of an image formed by a single objective is obtained directly through laterally displaced slits, and no other means would permit of such simple and convenient mechanism for taking the measurements.

The obvious objection to a grating is that the conventional type of opacity grating throws a great deal more light into the central image than into any of the spectra, and as only one of the spectra is utilised the illumination would be very much more feeble than with a prism; but it is not necessary to use a grating of this type. Thorp demonstrated the possibility, though not the commercial practicability, of making gratings which throw nearly all of the light into a single spectrum on one side, and the writer can make to order gratings which throw more than 50 per cent. of all the transmitted light into the first order spectra. It is a grating of this character which is used in the new colour meter, with entirely satisfactory results. Many things which have had to receive careful consideration may be best understood after a more detailed description of the perfected instrument and its operation has been given.

Fig. 1 is a vertical plane of the optical part of the diffraction colour meter. A, A', is a line drawn through the optical axis; B, is the central slit for ordinary light; C, D, E, the lateral slits for blue, green, and red spectrum rays; F, the grating, covering half of the field; G, a telescope objective which forms an image of external objects and background in the divided field; H, a diaphragm to cut light from the central slit out of the half of the field covered by the grating. The lens, J, is of such focal length as to exactly parallelise rays from the central slit B, and the lens K, to converge them to the eye slit at L, from which the field is seen evenly illuminated.

The slits and mechanism are all on the outside of the case, and adjusted by micrometer screws acting on levers, conveniently close to the eye. The levers are short and rigid, with a lateral extension and support, because they must work without any wobble or back-

covered slits for the three-colour mixture on the other, while a lens placed in front of the four slits forms an image of external objects, which looks like an ordinary single telescopic image divided by a vertical spider line in the eye-piece. The image in the right half of the field is produced in the simplest manner, by light transmitted through the central slit; the image in the left half of the field is formed by a mixture of rays transmitted by the three lateral slits, and in using the instrument as a telescope this half of the field would not appear illuminated at all but for the presence of the diffraction grating, which bends parallel to the axis blue-violet rays from the central slit, green from the second, and red from the third, the mixture matching the ordinary white of the right side of the field. Assuming that the instrument is directed to a surface of standard white, over a portion of which is placed a sheet of coloured material to be measured, it will be evident that by so directing the telescope that the coloured object fills the right field just up to the dividing line the left field can be made to match it, both in hue and luminosity, suitably reducing the apertures of the colour slits. These slits are ruled in a dividing engine, through an opaque film on glass,

lash. The obvious method of construction would be to have the micrometer screws act directly upon the slit sides; but that would bring them too far from the eye for convenience of operation, and would also necessitate the use of special differential scales. The use of levers permits of adjustment for different total apertures by simply sliding the micrometer screw mount along the arm of the lever, leaving the scales all alike. These advantages are of such importance that, although I at first experienced great difficulty in devising and fitting lever movements that would be "dead beat," I persisted, until I believe I have achieved perfect success.

Inasmuch as the setting of the slits must be accurate to 1-100 of a millimeter, it would be unreasonable to expect such fixtures to retain their adjustment, and provision is therefore made for quickly testing the adjustment and perfecting it in a few seconds if it proves not to be right as found. This, I am convinced, is a wise provision to make, whatever the character of the mechanism, and it serves in this case to permit of such important reduction of cost of manufacture as might very well make all the difference between success and failure as a commercial proposition.

The slit spacing is calculated to superpose wave-lengths 43, 53, and 66 on the image of the central slit at the eye slit, when all three of the colour slits are half closed; the measurements are therefore made in definite terms. The absolute aperture of the open slits has been found by trial and error, to make the two halves of the field exactly match on a standard background. This is necessary because the extraordinary brilliant gratings used do not give a perfectly normal distribution of light through the spectrum. This adjustment having been made, a position was found for the bearing of the respective micrometer screws, which made them exactly close the slits when the pointer was turned from 100 to 0 on the attached scales, thus dividing each slit opening into 100 parts, although the absolute opening is alike in no two. That the instrument is in adjustment can be proved by several experiments, one of which is to partly close the central slit, when it will be found that the three pointers must be turned down the scale equally to match the white or lower luminosity.

If the colour meter be now directed to a house across the street, a single image will appear in the field, with a vertical hair line division through the centre, and although the right half of this image is formed through the central slit and the left half exclusively by rays passing through the three lateral slits and then bent parallel to the axis by the grating, making a mixture of red, green, and blue-violet spectrum rays only, at the eye point, the two halves of the field may appear exactly alike to the eye. Directed to an evenly illuminated standard white background, the two halves of the field appear exactly alike, of an even neutral white. The light transmitted by the central slit to the right half of the field is matched in the left half by spectrum red (R) 100, spectrum green (G) 100, and spectrum blue-violet (B) 100.

If, now, that part of the background which covers the right half of the field is covered by a sheet of coloured paper, certain kinds and quantities of the coloured rays filling the left half of the field must be cut off in order to make the two halves match again, and the quantity remaining is a measure of the colour and luminosity of the paper in terms of R, G, and B spectrum rays. Assuming that the scales read R 50, G 20, B 60, this colour can at any time be reproduced by pointing the colour meter at a standard white background and setting the indicators at those figures, provided that at the time it is done all slits exactly close by turning the pointers down to zero, which can be determined by trial in a few moments. If it is now desired to see if a new sample of coloured paper matches the old one, which meantime may have been lost or changed colour by fading or otherwise, the new sample is placed on the white ground so as to appear in the right half of the field, and any difference from the old sample will be at once apparent.

There is an aperture in the case at the left of the eye slit, through which the three colour slits can be seen directly, and watched while opening and closing to see that the movement is smooth, and that they close exactly alike at top and bottom, which they will if the slit sides are in place on their runners and the slit fingers have not been bent. The best way to test the accuracy of their setting for zero is to turn two of the pointers past the zero point (by lifting over the stop) to secure an absolute cut off of light from the respective slits, then turn the remaining screw while looking through the eye slit. The field should just go back when the pointer is turned down to

zero, and then show a trace of light when turned up two divisions of the scale. If it does not, hold the pointer to zero and adjust by turning (with a screw-driver) the inside pin screw. Test the other two slit adjustments in the same way. The adjustments may stand true all day, but temperature changes are liable to affect it. The image of the central slit must also fall exactly in the middle of the eye-piece slit. This can be determined by looking at the eye slit through a small magnifier, provided for this purpose, and if readjustment is necessary, it is effected by a slight lateral displacement of the eye-piece slit.

A point which may be noted about the reading is that the difference between the highest scale number and 100 represents black, and the difference between the lowest scale number and zero represents white. Thus the reading R 50, G 20, B 60, indicates 40 per cent. black and 20 per cent. white, degrading a hue which is three parts of red to four of blue. While considerations of this nature are interesting and have their uses, the simple numerical expression R 50, G 20, B 60, serves every purpose for record and reproduction.

While the description which I have given will doubtless serve to make the operation of the new colour meter sufficiently clear, the subject is far from being exhausted, and I cannot close without discussing briefly some other pertinent matters.

In the first place, in order to make measurements having a high degree of precision, the spectrum colours with which the measurements are made must be taken from the right places in the spectrum and in sufficiently narrow, isolated bands. This is determined by the focal length of the collimating lens, the dispersion of the grating, the spacing of the slits, the width of the colour slits, and the width of the eye slit. In this instrument the spectra at the plane of the eye slit are nearly one cm. long, and so pure that the Fraunhofer D, E, and F lines look sharp under a 2½ in. magnifying glass, while the R slit is one-third open, and the G and B slits half open. Practically, therefore, the degree of purity and isolation of the spectrum colours depend chiefly upon the width of the eye slit, which determines how wide bands of the substantially pure spectra shall enter the pupil of the eye. The eye slit is 1 m.m. wide, and therefore pretty sharply defined bands of spectrum colour are utilised, each not more than one-tenth as wide as the entire spectrum. In determining a standard for this adjustment two factors had to be taken into account—namely, aperture of field and luminosity. The image, the first on account of the yellow spot in the retina, and the second because the illumination may be either too weak or too intense to favour a high degree of accuracy in making observations. The shorter the focal length of the field lens, the larger angle the field subtends to the eye, and the smaller the spectra projected at the eye slit. The smaller the spectra at the eye slit, the narrower that slit must be made to secure a given degree of purity of spectrum hue. The narrower the eye slit, the feebler the illumination. The field subtends too small an angle to the eye, too much of the image falls upon the yellow spot of the retina, which, while it is the best part of the eye for distinct vision, is comparatively insensitive to peacock-blue spectrum rays, and makes a high degree of accuracy of measurement out of the question, especially as the yellow spot varies greatly in size and depth of colour in different individuals. The image on the retina must be large enough to cover a considerable area outside the yellow spot, and this is first of all provided for. If the illumination is too feeble, the sensation of colour is not sufficiently excited, as witness coloured objects seen by moonlight. If the illumination is too intense, it destroys the sensitiveness of the retina; and this is so far true that Sir William Abney requires a rest of the eyes in darkness for some minutes before making eye tests with his colour patch apparatus. With a six-inch focus field lens, 1½ in. in diameter, and 1 m.m. eye slit, the field is large and well illuminated.

In short, to meet practical requirements, certain compromises had to be made; and if they are made intelligently, with a full comprehension of the nature and relative importance of all the factors involved, the result will be, and in this case is believed to be, worthy of acceptance as a permanent standard.

The analysis colours must be just pure enough so that the pure reds, greens, and blues that are met with in the arts and industries can be perfectly matched; the deepest ruby, green, and cobalt glasses, and deep shades of the most brilliant coal tar dyes, particularly the violet purples. There was no difficulty about the purest blues and greens that could be obtained, but in order

match certain reds and aniline violets I had to take my red slit rather towards the end of the spectrum than would be necessary with a narrower eye slit, and then to make the red slit wider than the others in order to make a white of the mixture. The practical efficiency of the combination finally adopted was proved by careful tests with coal tar colours in combinations adjusted to show narrow transmission bands in the spectroscope, but not until the slit fingers had been very accurately fitted and the inside of the case specially lined and diaphragmed to prevent any scattered light from reaching the grating.

The theoretically higher degree of accuracy which might be obtained by sacrificing all considerations of commercial expediency would therefore never be detected in using the instrument for those purposes for which it is designed, and for which it is certainly far more accurate than any device which involves the multiplication of reflecting surfaces to secure increased absorption. In this connection, it may be pointed out that two pieces of pot-coloured glass, the sum of whose thickness is two m.m., have not the same value as one piece two m.m. thick, and the diffraction colour meter will measure the difference by several degrees of scale.

Admitting that one of these instruments is calculated to meet every practical requirement, there remains only the question whether exact duplicates of it can be made with certainty, so that there shall be no doubt about the readings of different instruments being alike. The gratings are all casts from one original, exactly alike, permanent and unchangeable. The slits are ruled on a standard make of ruling engine, with definite settings and feeds, and are also exactly alike, permanent and unchangeable. Other parts are made to gauge, and the only thing that would be likely to introduce any error is want of uniformity in the focal length of the lenses used. They are made to order, and supposed to be alike; if they are not, the error is small, it suffices to see that the extension of the eye-piece is right to make the image of the slit and spectra focus exactly on the plane of the eye slit, and wave-lengths 43, 53, and 66 m.m. the colour slits will then superpose in the middle of this slit, required.

It is necessary to state that because there is a perceptible change in luminosity of each analysis colour in passing from one edge of the eye slit to the other, the field must be viewed with the eye slit passing the pupil of the eye centrally. This is ensured by bringing the eye back to a point where the right and left edges of the field are slightly and equally cut off from view by the edges of the slit. There is still one other point which I must touch upon, though very briefly, and that is the relative facility and accuracy with which different individuals may be expected to make colour measurements with the instrument. Much will, of course, depend upon the practice, but after a few hours' practice pretty accurate measurements could be made and verified by repetition in from one to five minutes, provided that the operator has normal colour vision. Our blindness, even in small degree, is fatal to accuracy. Even the normal eye is very much more sensitive to percentage changes in some colours than others, and it is well to know that small errors are apt to occur by reason of such known facts as that two per cent. of any colour may be added to a perfectly neutral white without being recognised as colour. Such limitations are introduced by the eye, and may be charged up against the colour meter.

The purest colours can be matched the quickest. For instance, a very deep and pure red, obtained by combining screens of aniline red and yellow, is matched by closing the blue and green slits completely, and then moving the "red" pointer down the scale until the luminosities match. It can be done with considerable precision in four or five seconds. On the other hand, if the red is of a slightly orange hue and at the same time not of very high luminosity, it is difficult to get exactly the right minute proportion of green and red to both hue and luminosity match. Pale shades of purple reds are rather difficult, balancing the red and blue with just the right amount of green and in the right quantities to match both hue and luminosity. All kinds of greens, blues, and yellows, strong or weak, are comparatively easy to match.

Something should be said about standard white backgrounds, but have not yet done much with that part of the subject, and will now only state that for transparent objects nothing could be better than a white background when it is raining or foggy.

In conclusion, I would point out that the same instrument, with

sunlight or electric arc focussed exactly on the eye slit, becomes a perfect projection colour patch apparatus, much more convenient than anything heretofore used for that purpose. I have, however, devised a modification still better adapted for that particular purpose, with increased illumination by use of both right and left spectra, and this device will be the subject of another paper.

F. E. IVES.

## Photo-Mechanical Notes.

### Etching Metal Plates.

A PATENT has been taken out by Johann Axel Holmstrom, of 3, Via Palestro, Rome, in reference to a method of etching articles of metal, etc. The article is mounted in a holder and submerged to a suitable depth in the etching liquid contained in a vessel, and a movement of the article in reference to the liquid then takes place in a direction at, preferably, right angles to the surface to be etched. The claim of the specification (No. 28,679, 1906) is:—The method of etching consists in the article to be etched, carried in a holder, being submerged in the etching liquid, the article or the liquid or both being then moved in such a direction that the liquid strikes the surface of the article preferably at a right angle.

An increased pressure of the liquid against the surface to be etched is effected during the relative movement between the article and the liquid, which pressure results in the generated gas bubble being removed from the surface and in the liquid acting more effectively and rapidly, at the same time the advantage is gained of a rubbing action between the article and the liquid, which action is desirable, especially on the plates. Further, the article being suspended freely in the liquid, eroded particles, especially if the surface to be etched is directed downward, can sink to the bottom of the vessel and consequently do not gather on the article, preventing access of the liquid to the same, as in the case of etching operations, in which the vessel is placed on the bottom of a rocked vessel, in which case eroded substance gathers on the surface delaying and interfering with the etching operation.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between July 29 and August 3:—

CAMERAS.—No. 17,467. Improvements in or relating to photographic cameras. Reginald Herbert Payne, 111, Hatton Garden, London.

PLATES AND FILMS.—No. 17,463. Improvements relating to iso- or orthochromatic photographic plates or films. Thomas Macwalter, 322, High Holborn, London.

X-RAY SCREEN.—No. 17,577. Improvements in and relating to apparatus for X-ray screening and stereoscopic photography. Frank Barrett, 1, Nassau Street, Dublin.

CINEMATOGRAPHS.—No. 17,597. Improvements connected with cinematograph exhibitions, partly applicable to other purposes. Thomas Ernest Raymond Phillips, 15, Water Street, Liverpool.

LENSES.—No. 17,624. Improvements in objectives for photographic purposes. Rudolf Steinheil, 6, Lord Street, Liverpool.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

CINEMATOGRAPH STANDS.—No. 24,952. 1906. The invention, which relates to the bases or supports for cinematograph apparatus, consists of a base of two side bars connected by cross stay-bars, the slide bars being grooved to receive the edges of the base of

the projecting lantern forming part of the apparatus. This lantern is adapted to be clamped in position by one of the side bars having a little free play on one of the cross stay bars, and being tightened against the flange of the lantern by a nut screwed on the end of the stay bar. A block or base plate is provided to slide upon some of the cross stay bars and serves to carry the cinematograph, suitable means being provided for clamping the block in any required position. Such means may comprise a bar designed, when rotated, to force one or more plates or grippers into contact with the stay bars, on which the block slides. Leo Vamin, 27, Powell Street, Goswell Road, London, E.C.

### New Trade Names.

**RYTOL.**—No. 294,399. Chemical substances used in photography. Henry Solomon Wellcome, trading as Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C., manufacturing chemist. July 6, 1907.

**SEPIANA.**—No. 294,375. Prepared paper for photographic purposes. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers, and films. July 6, 1907.

### Analecta.

*Extracts from our English weekly and monthly contemporaries.*

#### Exposures for Outdoor Nude Studies.

As far as practical photography is concerned (write Messrs. E. B. Vignoles and P.-S. Greig in "The Photographic News"), there is but little to note. The exposures necessary to get good gradation in flesh tones in sunshine on an open beach, using plates of 200 H. and D., 1/25 sec., with  $f/8$  at mid-day, will be found none too much, and among sand dunes this exposure may safely be doubled. Particularly is this the case when the beautiful effects of back lighting in sunshine are to be secured. Be careful not to carry development too far. Much may be done with a thin negative, but an over-dense negative is hopeless, especially for enlargements.

#### Reflex v. Scale-Focussing Hand-Cameras.

As there has been considerable discussion lately (writes Mr. Bertram C. Joy in "The Amateur Photographer") on the respective merits of reflex and scale focussing cameras, the experience of one who has used three or four types of the latter, and has had a reflex in use for two years, may be of some interest. For landscape work there are one or two more important advantages. It is possible in quite a few minutes with a reflex to examine a likely picture on the screen from ten or fifteen different points of view, a most tiresome business with a stand camera. Of course, when the best position is found, there is no reason why a tripod should not be set up and a lengthy exposure given if necessary. Then, again, it is surely easier to compose your picture when regarding it the right way up than if it were upside down, and moreover, the more erect position of the body when focussing with a reflex on a tripod is very much less tiring. In portrait photography no valuable time is lost while inserting the dark slide, as, of course, the slide can remain in focussing. The most formidable objections raised against the reflex appear to be the initial expense, excessive weight, and the fact that the camera with its hood erected is rather liable to attract inconvenient attention. The first is unanswerable, except by suggesting that the best is perhaps the cheapest in the long run. The second objection, in the case of larger sizes than quarter-plate, also holds good, and personally I do not see the possibility of much reducing the weight of a 5 x 4 reflex. The third objection is, like the first, unanswerable, and it requires considerable tact to work among a crowd of people without attracting undue attention, and possibly spoiling an otherwise good picture. With due regard to these objections, however, I should think it very unlikely that any user of a good reflex would willingly go back to the scale-focussing system. I am pretty certain I shall not.

### New Books.

"Photographisches Rezept-Taschenbuch." By Paul Hanneke. Pp. 176,  $6\frac{1}{2}$  x 4. Berlin: Gustav Schmidt. M2.25.

This collection of formulæ is smaller than a good many similar works, but none the worse for that, since its preparation has evidently been carried out with due regard to the provision of convenient reference book for practical work. For such a task Herr Hanneke, as editor of our contemporary, "Photographische Mitteilungen," and a member of the scientific staff of Act Gesellschaft für Anilin Fabrikation, is well qualified, and, as a result, we are spared the repetition of formulæ which have a *raison d'être* above others, and are therefore only a source of mystification to those consulting such a volume. The volume deals with the usual formulæ of developers and solutions for the treatment of negatives, of backing mixtures, and varnishes. Collodion and collodion emulsion processes are dealt with, as also the various printing processes. Herr Hanneke's book should be a welcome addition to the photographic formularies.

### New Materials.

Permanent Vitrified Copper Enamels. Made by the Autotype Company, 74, New Oxford Street, London, W.C.

We have been favoured by the Autotype Company with the opportunity of inspecting a number of ceramic photographs, such as they are prepared to execute for the photographic profession, in whose hands the company very rightly hold, a profitable return is obtainable from the supply of this beautiful and permanent form of photograph. Our long experience of the Autotype Company in the pigment process of photographic printing should be sufficient guarantee of the excellence of their work, in what is, perhaps, the most perfect application of such processes; but we may, nevertheless, record our admiration of the technique of the enamels we have seen. The company offer three stock sizes, each being obtainable either circular or oval, of colour either red chalk, photo brown, or warm black. The larger sizes, 1½ in. and 2 in. in diameter, are particularly well suited for presentation purposes, and are supplied from a negative of size at the prices of 12s. 6d. and 15s. respectively. If from a plate a charge of 2s. 6d. is made. The enamels are prepared on a copper base, and exhibit in the specimens before us the retention of all quality of the negatives which is characteristic of a good ceramic photograph. A portrait of this class, if offered to a customer such a way as to impress its special features, should be a frequent source of profit to photographers with anything like a connection for good use may be made of the fact that nothing short of wilful destruction can impair the beauty of the portrait. The Autotype Company, we would add, have prepared a convenient circular showing the exact sizes and shapes of the enamels.

#### CATALOGUES AND TRADE NOTICES.

THE CHARLES URBAN TRADING COMPANY, LIMITED, in their price list for August, give detailed particulars of their specialties in bioscopes and animated picture accessories, together with a summary descriptive of their latest film subjects.

MESSRS. EMIL WUNSCH, A. G., of London and Dresden, send a copy of their latest price list, which contains particulars of the most recent novelties in photographic apparatus. The hand cameras manufactured by this firm appear to be specially worthy of note, they combine the features most desirable in this class of instruments together with light weight, at moderate prices. The "Wunsche" series of telescopic metal tripods can be adapted for use with classes of cameras, and, being light in weight and folding into a compass, are specially suited to the needs of the tourist or cyclist.

**A LONDON AGENT'S BANKRUPTCY.**—At the London Bankruptcy Court, on Tuesday last, the public examination was appointed to be held of James Stroud Nunn, residing at 18, Clifton Road, South Norwood, S.E. In the course of the proceedings it transpired that the debtor described himself as a photographer's assistant and director of Satino, Ltd., Nunn and Co., Ltd., and The Mid Surrey Vacuum Cleaner, Ltd. He commenced business in September, 1905, at 11, Queen Victoria Street, E.C., under the style of The Mid-Surrey Vacuum Cleaner Company, holding a licence from the petitioning creditors for that purpose. He borrowed £35 from Mr. Farrow, chairman of Farrow's Bank, to enable him to make a start, and afterwards he borrowed further sums from that gentleman. In July last year he started another business at the same address as manufacturers' agents, under the style of J. S. Nunn and Co., and Mr. Farrow agreed to finance that business for him to the extent of £1,000 on the security of the future book debts and the stock. The only part of that business that prospered, however, was the photographic branch, and further capital being required for that department, Mr. Brooks, the manager, expressed his willingness to put money into the concern, provided it was made into a separate business. The result was that in February last a company was registered, under the title of Satino, Ltd., which took over from the Nunn Company the photographic branch of their business. The Nunn Company received £328 (£1 shares) in Satino, Ltd., and a debenture for £500, representing the absolute value of the stock, etc. The debtor became a director of

Satino, Ltd., without fees, but he received £2 per week as an officer of the company. Among the stock sold to Satino, Ltd., was a parcel of Falla Gray gaslight photographic paper, the invoice price of which was £35. He estimated that he owed about £500, and attributed his failure to the action of the petitioning creditors in withdrawing the licence under which he carried on his business. The examination was ordered to be adjourned.

**MASTER AND SERVANT.**—A somewhat unusual claim for wages by St. Albans employees came before the City Bench last week. Mr. A. H. Brown, of 4, King's Road, St. Albans, sued Mr. J. R. Sykes, of Sidcup, Kent, for £1 12s. 3d., one week's wages. Mr. Sykes, he said, was the manager of the Cerio Photographic Company, carrying on business at Kingsbury Works, St. Albans, and with registered offices in Aldersgate Street, London. Some time ago it was proposed that some of the employees should go on half-pay, because the works were to be shut down for a few days. Afterwards, however, it was agreed to pay them two-thirds while the works were shut down, and to subtract the difference between half-pay and two-thirds from the full pay when they began work again. The full wage agreed upon was 35s. per week. Complainant claimed that there was £1 12s. 3d. still owing.

Cross-examined by Mr. S. M. Robinson, who appeared for Mr. Sykes, witness admitted that there had been no work turned out since the arrangement regarding two-thirds pay. Mr. Robinson said this was a limited liability company. Some time ago an official receiver was appointed, and everyone was dismissed except five men. There had been an arrangement made whereby two-thirds pay should be given until the works should be re-opened. But the works were never re-opened, and the complainant therefore had no claim. Even if he had a claim, explained Mr. Robinson, he was suing the wrong man, for Mr. Sykes was not his employer, but Mr. Gunery, the official receiver.

Mr. Sykes, the works manager, said that on June 20, the debenture holders of the company appointed a receiver. Notices were posted up all over the works stating that the receiver had been appointed. After lengthy consideration, the magistrates came to the conclusion that the case must be dismissed. Mr. Toulmin said he thought Brown had been wrongly advised. Three other cases, standing in the names of J. P. Taylor, J. W. Mann, and William Gernat, who also sued Mr. Sykes for wages in connection with the same arrangement, were dismissed by the Bench, on the ground that the wrong person had been summoned.

**BERNARD COOPER, LTD.** (Photographers, London).—A debenture, dated July 19, 1907, to secure £125, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holder, Mrs. M. M. Hadfield, 155, Fellowes Road, Hampstead.

**THE PHOTOGRAPHIC CRAZE.**—A young man, of respectable appearance, admitted, before Sheriff-Substitute Davidson, at a pleading diet, the County Buildings, Glasgow, on Tuesday last, the theft of six cameras, a number of dark slides, four plate adapters, and five packets of film envelopes with films, from a shop in West George Street, between the month of February and July 8. Mr. Marshall, writer, who appeared on behalf of the accused, said his client had borne a good character. He was three years in his present employment, and twelve years in his previous situation. He was engaged as a photographer in a large public works, where it was his duty to take photographs of the machinery, etc., and he became a photo enthusiast. He took part in several competitions for photography, and received many awards in the form of gold and silver medals. His passion for the camera had led him to commit the offence. He had not sold any of the articles mentioned in the charge, all of which had been recovered by their owner, who was very anxious that the accused "should have a chance in life for his poor wife's sake," and suggested that he should be dealt with under the First Offenders Act. His Lordship said he could not regard the thefts as a first offence, considering the period between the months mentioned in the charge. He passed sentence of three months' imprisonment.

#### NEW COMPANY.

**S.P. SYNDICATE.**—August 1. £525 (500 £1 ordinary and 1,000 6d. deferred). Manufacturers of and dealers in the composition known as "Synoloids," chemicals, photographic and scientific appliances, and apparatus, etc. No initial public issue. First directors (not less

than three nor more than seven) to be appointed by signatories. Remuneration 5 per cent. of the total number of shares which the company shall be entitled to receive in respect of the promotion by of any new companies or assistance by it in the formation thereof, whether such shares shall be fully or partly paid, divisible. Directors ceasing to hold office before the receipt of such shares shall not be entitled to any remuneration for their services.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed our correspondents.*

#### METOL POISONING.

To the Editors.

Gentlemen,—For the benefit of "A. T.," in "Answers to Correspondents," in the "B.J." of August 9, and for the good of fellow workers, I would like to state how my father and myself cured ourselves of the terrible metol poisoning. We did it in the following way:—First, having got a small gas stove, we placed a pan of water on it, and into this we put our fingers, then lighted the gas and let the water boil with our fingers in it. By doing this we were able to stand a greater heat, and by that means scalded the poison out. We did it night and morning. Trusting you will be able to make use of this and hoping that it will be the means curing several of my fellow readers who suffer from the effects of metol, I remain, yours truly,

T. L. HAMPSHIRE,  
25A, Spring Grove Street, Huddersfield.  
August 8, 1907.

To the Editors.

Gentlemen,—It is surprising to me that we do not hear of more cases, such as appear under "Answers to Correspondents" this week with reference to the above. I have commented upon the matter various times, but, am afraid, without offering any suggestion of remedy. Recently I had the thumb and forefinger of my right hand in a most deplorable state as the result of some dark-room operation when my rubber gloves had got mislaid, and I used those two members in the nude, so to speak. I had thought of taking photographs of them on an exaggerated scale to demonstrate the effects, but was too busy trying to heal them with poultices and subsequently cold cream. I have discovered, however, that it is possible to use the bare fingers with these powerful developers and avoid the painful results by the comparatively simple method of very thorough washing of the hands after the work. Many persons will be constantly rinsing their hands under the tap, under the impression that they are doing all that is necessary, not to mention the fact that the fingers will be probably dried upon a towel, clean to the eye, but most probably far from chemically clean. This mere rinsing is of no use whatever. I am particularly sensitive to metol effects, but if I take care to wash my hands very thoroughly in hot water, with plenty of good soap and a stiff brush, using after this important operation a towel which is beyond reproach, I experience no ill effects; but the washing may be very thorough, equal to at least six average washings, to put it strongly.

If we use bichromates we get stains clearly visible and removable by plenty of washing in alum solution, and subsequent thorough washing. If we get the fingers stained with iodine we know what to use, and we set to work, and are not satisfied until the stain is dissipated and the hands clean once more. The developer complain of leaves no visible stain, but it does its fell work just the same, and all the more freely, because we may decide that the simple washing is sufficient. Obviously we want to discover something which will act as an antidote to this poisonous effect. I think if a few victims were to make trial something might be discovered to help matters. I have referred to the very thorough wash with hot wa-

soap and brush, vigorously indulged in, just as though a visible stain was to be removed. An aid to this cleansing is the addition of the hot water of a few drops of liquid ammonia (which may be fumed), or any of the water softeners sold commercially; borax powder therefore may be used. I am inclined to believe also—though I might find it difficult to explain the reason why—that a rinse of fingers in a sulphite of soda solution prior to the soap and water, helps.

It is certain that the metal stain, as I think we may call it, is removable by washing, also that the operation is assisted by the water being made slightly alkaline with the ammonia, or soft with the alkali compounds. What can be suggested now to further simplify the cleansing?  
J. PIKE.

#### PEDLAR OR ——— ?

To the Editors.

Gentlemen,—The leading article in your last issue is exactly one of those which we expect from the old "B.J.," but if your view is correct and is upheld in one of the higher Courts it will be a most serious matter for those firms that cater for this particular class of business. It must, on the one hand, either force the peddling firms entirely to cease their itinerant importunities or incur the expense of legal habitation for a month. Would the latter then be sufficient to deter the firm from peddling? It is not the small man that hurts.

It is the large firm with a big central establishment that can afford to produce work at a low price that hurts. Truly, gentlemen, you are somewhat hard on some of us, when you say that we are less skilled craftsmen than the peripatetic tinker or trimmer. One can only imagine that you were thoroughly imbued with the unconsciously absorbed principles of the author of "Art and the Camera," who, to quote your own words, "has never a suitable word" for the professional photographer. Or else you are misled—this is a true Scotch word—the old tale, "Punch's." I am, about the Italian organ-grinder, who would not speak to the meat man, because the latter was a tradesman, and he was a professional. Any way, I am grateful to the old "B.J." for the article, and our head constable has had a marked copy from Edinburgh.

"A DEIL I' THE FECHT."

Without any desire to belittle photographers (we hope our correspondents will give us the credit of this much), we think we were not stepping the mark when we said that the canvassing photographers, as craftsmen, are, many of them, inferior to peripatetic knife sharpeners and chairmenders, who are usually very well up in their business. Our contention was, and still is, that if a pedlar's licence is proved to be necessary to the canvassing trade, a very desirable check will be administered to the proved dishonest and wilfully fraudulent practices of such trade, which practices, without a shadow of doubt, have injured photography as a whole.—Eds. "B.J."]

THE BLENHEIM CLUB has recently acquired a spacious and well equipped studio for the use of members at 53, Pall Mall, within a few minutes' throw of St. James's Square. Access by members may be obtained at any time between the hours of 10 a.m. and 10 p.m., by applying to the porter at the Blenheim Club.

PHOTOGRAPHY BY WIRE.—Mr. Thomas H. Norton, the United States Consul at Chemnitz, in a report to the Washington Bureau of Manufacturers, says that much attention is now laid in Germany to the remarkable measure of success which has attended the application of Professor Korn's invention for the transmission by means of photographic reproductions over long distances. His latest experiments show that nearly as satisfactory results are secured by the use of the ordinary telephone wires as on lines especially constructed for the purpose, the only difficulty encountered on telephone wires resulting from calls on adjoining wires. These cause the formation of zigzag lines on the reproduced picture at the receiving end, which are easily corrected by retouching. Alterations in intensity by ringing on or ringing off, as well as during conversations over adjoining wires, are without effect. It is further stated that the wire employed for photographic reproduction can simultaneously be utilised for telephonic conversation.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

#### PHOTOGRAPHS REGISTERED:—

Frederick Tom Blackburn, 17, High Street, Bndleigh Salterton. *Photograph of The Arch, Ladrham Bay.*

Herbert John Jackson, Fern Cliff, Stoneleigh Road, Kenilworth. *Photograph of La Milo (Miss Pansy Montague) as "Lady Godiva," taken at Coventry, August 7, 1907. The photograph was taken in the street and the background taken away.*

VARNISH.—Would you be kind enough to give me a recipe for making a varnish that will rise from a glass support with a gelatine print to protect same from moisture?—A YOUNG READER.

The best varnish for the purpose is collodion. Rub the glass plate over with French chalk. Then coat it with enamel collodion, and when that has thoroughly set, place the plate in water until all greasiness disappears from the film. Then bring the wet print in contact and squeegee together. When dry and stripped off, the collodion will come away with the print, and will perfectly protect it from moisture.

REPAIRS.—About a year ago we bought the above business. The lease (repairing) is for fourteen years, with three years to run. It was transferred from Mr. ——— to us by the landlord, and the rent is £65 a year. Recently we noticed that the woodwork of the studio is quite rotten in many parts, and it is in a really dangerous state. We have been to the landlord about it, and he says it is no affair of his, and that we must do the necessary repairs. As the rotting must have been going on for years before we took the place, and as something must be done at once, as we are afraid that the side of the studio will be blown in with a heavy wind, can we do what is necessary and deduct the cost from the next quarter's rent?— ——— AND Co.

No, you cannot. As you have the place on a repairing lease you will have to do all the repairs, and if the lease is on the usual terms you will have to leave the premises in tenable repair on its expiration. Persons when they take over leases should duly consider the state of the repair of the premises at the time, and the responsibilities they incur, and make due allowance for them before closing the transaction.

COLOURING.—Could you tell me what to use on glossy bromide postcards so as they will take water-colours—something that will give them a tooth?—MORRIS.

If you wish to get a tooth, you can obtain it by rubbing the surface over with an ink eraser—but, of course, that will injure the gloss. We would advise you to employ the colours that are specially sold for this class of work, as with them the print requires no preparation. They are to be had from any of the large dealers.

SPIRIT SENSITISER FOR CARBON TISSUE.—Some little time back you spoke very favourably of a new spirit sensitiser, sold by the

Autotype Company. Do you consider that tissue sensitised with it is as good for commercial work as that sensitised in the usual way? Our business in carbons, portraits, is mainly cabinets and panels. If this sensitiser is as good as the ordinary it would at times be a convenience to us. Your kind reply will be esteemed by — and —.

From our experience with the sensitiser we consider that it is quite as good. Indeed, we may say that tissue sensitised with it works better than that sensitised in the ordinary way, when the latter is dried under at all adverse conditions.

**DISTORTION.**—I am sending you five portraits, large heads, which have been rejected by sitters. I think you will admit that they are good photographs, yet the customers will not have them. They find no particular fault with them, only that they do not like them. I should not have troubled you over these five pictures except that I have so many re-sits with large heads, which I do not get with other sizes. Can you suggest the reason?—**ONE YEAR IN BUSINESS.**

The reason the portraits are unpleasing is that they are "distorted," or, rather, that the perspective in them is very violent. This is due to a lens of too short focus being used for taking the pictures, so that the camera had to be placed very close to the sitter. If you use a lens of double the focal length of the one employed for these portraits you will find the pictures will give greater satisfaction. Large heads taken with a very short focus lens scarcely ever give satisfaction, either to the sitters or their friends.

**APPRENTICESHIP.**—Three years ago I took a young fellow, aged nineteen, as an apprentice for three years, at a progressive salary. The indentures were properly drawn out by a friend engaged in a first-class solicitor's office, but they were not stamped. Now I have taught the young chap the business, and he has become a really useful hand. The other day he told me that unless I doubled his wages he would get another place, which he said he could do, as the indentures were not stamped. I believe he has had the offer of a berth at another photographer's near by. Will you please tell me what legal proceedings I should take in the event of his leaving me, as he might do an injury to my business?—**NORTH COUNTRY.**

You can do nothing. As the indentures were not stamped they are not binding on either party. The man is merely a weekly servant, and can leave at any time on giving a week's notice. Even if the indentures had been stamped the apprentice could not be compelled to serve after he had attained the age of twenty-one.

**WET COLLODION.**—During the last two winters I attended a good number of lantern shows, and was much struck with the superiority of wet collodion commercial slides over those produced by amateurs on gelatine lantern plates. The former were all more brilliant and clearer than the latter. I have been reading the articles that have appeared in the "Journal" during the last few weeks, and write to ask you if you consider the wet collodion process is too difficult for an amateur to take up for making lantern slides with a fair promise of success?—**LANTERN.**

Certainly not, if you follow the instructions carefully. You should bear in mind that, until the advent of dry plates, amateurs had perforce to work the wet collodion process for all purposes, even taking views away from home, yet they produced excellent results. In working the wet collodion process the chief essentials are extreme cleanliness in all the operations, and neatness in working. You must not be discouraged if your first few essays are not perfect successes.

**METOL POISONING.**—For the past year I have been using metol or metol-hydroquinone for my negatives, as I find the former brings out more detail than I can get with any other developer with snap-shots. Now I am suffering badly from the metol. My case is just the same as has been so often described by other sufferers. Can you tell me the best and surest cure?—**R. J. COX.**

The best and surest cure is to abandon the use of metol altogether, then Nature will quickly work a cure. Much metol poisoning might be avoided—indeed, entirely—by neatness in working. There is no necessity for more than just the tips of

the forefingers and thumbs to come in contact with the solution and they are not likely to be injured. It is only when the developer gets on the backs of the fingers and between them, on the backs of the hands, that trouble arises. If you must continue to use this developer, you had better wear india-rubber finger-stalls, and take care that the solution does not come in contact with the naked flesh.

**A DISPUTE.**—I beg again to seek advice on the following, and shall be glad if you will find space in this week's issue of your valuable columns. A man came to me some time ago and asked me to go to a place some five or six miles away from here to take some photographs of the interior of his billiard hall. I quoted him 10s. 6d. for six negatives. He agreed price was right. Then he wanted to know what I would do him a gross of postcards for, and I quoted him 12s. 6d., as he informed me he would want a set of them. I did this work for him, and asked him if I may take another set from different positions, and he assented. When I saw these latter negatives he liked them better, although the first negatives were taken to his order and under his own personal supervision. As his order was then completed off first lot, could not be at the loss to print another from last negatives. I would not pay for them for some time, and I had repeatedly set in my account. However, just recently he sent round to me a note, stating that he could not settle this account in its present form, stating at the same time that he had not had the negatives and therefore was not going to pay for them. As these negatives were of no use to me I took them round to him, and told him he might have them if he cared to pay or buy them outright. I take it there was not such a good sale for these cards as expected, and therefore he refused to accept the negatives, I left them on his table, where he had placed them. He asked me to take them from him, but I would not. Later he brought them round to my shop and threw them on the door-mat, and the consequence was they became all broken up. What can I do with such a man?—**M. H. J.**

The question is, Did you quote him for photographs or negatives? If the latter, he may be able to make you deliver the thing though there is a good case for the defence that he never asked or stipulated for negatives. We advise you to sue him for the amount of your account, based on the first lot of negatives. The second set does not affect the matter, so far as we can see.

**DAGUERREOTYPES.**—(1) We have had a whole-plate positive on glass (Daguerreotype) brought to us to be restored. Can you give the name of a competent man who could undertake this? (2) The probable cost of restoring it?—**C. J.**

(1) E. W. Foxlee, 22, Goldsmith Road, Acton, W., to whom apply for an estimate as to cost, which in any case is not great.

**OPERATOR.**—If you were engaged at 28s. a week you are entitled to that salary up to the time your notice expires. If you make no arrangement as to your railway fare being paid we do not think you can recover anything for that. You will have to leave according to the fortnight's notice at its expiration.

**C. C.**—One ounce of strong hydrochloric acid in 100 oz. of water will usually remove the colour from a pyro-metol stained negative, and we have not found it to return to the extent which your letter suggests, although it is quite true that a stain discharged with an acid bath is quite liable to return. We should recommend that you try the clearing solution headed "Sodium Hypochlorite" in the "Almanac," on page 965, using an extra quantity of the bleaching powder in the alkaline state. If made acid, suggested in the latter part of the paragraph, with oxalic acid there is greater danger of the image being at the same time reduced. Another plan which we have found of service in case of stain is to use a mixture of a very strong hypo solution and glycerine, using sufficient of the latter to keep the mixture fairly syrupy. If this is brushed on to the negatives, and they are allowed then to stand in the air for an hour or two, it will be found on washing that the stain has disappeared.

**ARTIFICIAL LIGHT.**—The favour of a reply to the enclosed query in this week's "B.J." will greatly oblige. I am at present doing midget photography by artificial light—i.e., incandescent gaslight. But as I wish to improve the present work, and as

take three-quarters, full-lengths, and groups, I shall be glad of a little advice and suggestions from you. You will see I enclose samples of busts, groups 2 and 3, and three-quarters of children. This is my limit. I cannot get anything decent beyond this. The trouble is the light. At present I can only use gaslight (as per enclosed sketches), the electric not being in these premises, otherwise, I daresay, this would see me out of my difficulty. I tried an extension of lights on the present apparatus, by placing an extra nine or ten underneath the apparatus. So I practically had lights on to the floor. But this did not light up the full-length figures properly, and groups not at all, in both cases making a nasty glare in the faces. So I give you particulars of how I have the light and work it, and do you think it is possible to arrange it differently with any good results? I have only a cheap lens (10s. retail price) that I take the enclosed with it. I use pyro-soda developer, "Warwick" extra-rapid plates, exposure three to four seconds, and use a trifle more soda than pyro. I have eighteen ordinary incandescent mantles, Bray's XXX (not enclosed in chimneys). But I don't quite get the full benefit of light, I know, as some of them don't quite hang perpendicular, consequently the mantle is not all lit. 1. Do you think the present apparatus can be arranged differently and altered, etc., so as to take three-quarters, full-lengths, and groups properly? 2. Also, what class of lenses do you advise for three-quarters, full-lengths, and groups, from midget work up to  $3\frac{1}{2}$  x 2 size? 3. Also, what class of lens to take postcard work in three-quarters, full, and groups? 4. What is your opinion respecting gas and electric? 5. Please state approximate cost of both lenses—really good instruments. You see I must have a short, very short, focus, combined with speed, and yet I want one to give roundness and good definition. My photographs have a flat look, and consequently take a lot of retouching. But perhaps this is caused by the present lighting.—C. EDWARDS.

1. Unless you can replace the four ordinary burners in the top row by incandescent we do not see that you can improve the apparatus at all. The work you send us is most of it too flat. We should say there is too much reflected light on the face. While you require all the light you can get on the lower part of the figures, you are evidently getting too much on the shadow side of the face. We should advise you to use a reflector pivotted like a looking-glass at its centre, so that the upper part may be pushed back, while the lower is pushed forward, or to use a less white material for the upper part of a fixed reflector. 2. We presume your present lens has an aperture of  $f/8$  at most, probably not that. If you can afford it, a large-aperture modern lens working at  $f/4.5$  or  $f/5$  would give you the same results with one-third to one-fourth the exposure, or with a second or two's exposure would probably enable you to secure groups. You will find prices in any large list, or in full in the "Almanac." The focus for a  $3\frac{1}{2}$  x 2 plate should be about 4 inches, which would allow you 8ft. from sitter to camera when taking a full-length figure upright on the plate. Such a lens will cost you about £4 10s. to £5. 3 and 5. A similar lens or postcard size would cost about £5 10s. or £7, and should have a focus of about 6 or 7 inches. 4. An enclosed arc lamp is of course very much better for your purpose (the groups) than incandescent gas.

NEGATIVES.—Will you kindly describe a quick and safe method of drying negatives? I am working on negatives for enlarging, and have a lot of trouble with spots and markings.—A. H. FLETCHER.

We prefer to mop off all surplus moisture from the film side with a piece of old soft cambric, and allow the negatives to dry spontaneously in a warm room (say some three or four feet above a gas stove), which they will do in a couple of hours. A quicker method is to immerse the washed negative in 10 per cent. formalin for fifteen minutes, rinse, pour almost boiling water over it, and dry before a fire. The method of soaking in two baths of methylated spirit (in each for about five minutes) is more expensive, and, owing to the mineral matter in the spirit, produces scummy markings in the negatives.

RIGHT.—Would you kindly advise me how to go about copy-

righting negatives? I have had a good run on theatre work, and I wish to reserve the copyright on all my work, and do I draw any royalty on all sales of reproductions?—EDWARD SUTTON.

Is it possible that you have never read the frequent replies to this query in our columns? You must deposit one print of each subject at Stationers' Hall and fill up the form of registration. You cannot, of course, describe yourself as the proprietor of copyrights in photographs for taking which you were paid. The copyrights in these cases belong to your customers. You had better study the article in the "Almanac" for 1906, or the "Notes on Copyright" in the "Handbook" of the P.P.A., of which body you should be a member.

MARKINGS ON NEGATIVES.—I enclose some untuned prints, showing distinct white patches on the right-hand side. Would you favour me with your expert opinion about them? My opinion is that some chemical (?) action has caused the marking, as in every case it occurs in the same slides on the side where cloth covers the pull-out panel of dark slide. This is somewhat out of the ordinary fogging difficulties.—C. W. SILENCI.

It is not uncommon to find fogged bands on a plate in the case of new dark slides, due very often to the traces of the polish on the woodwork, or cement used for the hinges. A day or two's exposure of the opened slides to light and air will usually remove the cause. One or two of the prints appear to be fogged from such a cause.

PHOTO FIXER.—We cannot say by inspection, except that the salts consist chiefly of hyposulphite of soda. A chemical examination would be required to identify any other constituents.

APPRENTICESHIP.—I was engaged with a photographer as apprentice for two years, salary to be paid monthly. Payment was very irregular. At the end of the time he asked me to stay on. As the work was congenial I did so. I was general assistant, doing most of his landscape work (one of the principal sources of his income), developing, operating when he was away, and assisting with the books, etc. Unfortunately I allowed matters to drift until my salary was several months in arrear. At the end of last year he became bankrupt, and the question is:—How many months' wages am I entitled to? His trustee has offered two months; but I believe the Act reads that all those engaged in professions, shopkeepers, clerks, etc., are entitled to four months', artisans and workers in trades, at weekly wages, are entitled to two months'. It may seem somewhat presumptuous to class myself as engaged in a profession, but I cannot afford to lose a few pounds, if I can help it.—W.

If you were engaged at a yearly salary, payable monthly, you are entitled to four months' salary. If, however, you were engaged at a weekly salary, payable monthly, you will only get two months' wages. Much will depend upon the terms of the engagement. You can claim the amount of salary in arrear over the two or four months as the case may be, but for that you will have to stand in with the other creditors.

SENSITISED HANDKERCHIEFS.—Can you inform me where I may obtain sensitised silk handkerchiefs through your "Answers to Correspondents" column?—ARISTO.

No such things are on the market. You might apply to the Platinotype Company. They might possibly supply some to your order. But we suspect you will have to prepare them for yourself.

PHOTOGRAPHS ON IVORY.—1. I shall be extremely obliged if you will kindly inform me where I can purchase small quantities of ivory for miniatures, and the best method of sensitising same for printing a brown image. 2. Also, where can I get some transparent colours that are permanent. I have tried several makes of these, and find that they are all aniline colours, which fade very rapidly indeed. I have had some coloured prints in the window (which faces the north) for about a fortnight, and every trace of colour has vanished. This is a serious thing to me, as I sell a lot of them every week.—MINIATURE.

1. Ivory in small quantities is to be had of all artists' colourmen. The best method of producing photographs on ivory is by the double transfer carbon process. All silver processes stain the ivory. 2. The most stable colours we know are those

sold by the artists' material dealers. Many of them are transparent, though not to the same extent as those made with coal tar colours, which are really dyes.

**WET COLLODION QUERIES.**—As I occasionally employ the wet collodion process I have read with interest "The Wet Collodion Process in Practice." I do not, however, quite understand the section on "Developing Dishes," p. 536. I should be glad to know where such "wave baths" may be procured for small sizes, for notwithstanding the well-known expedients of re-bathing the plate in silver bath before developing, spirit in developer, variously lipped pourers, I constantly spoil plates by not getting a regular uninterrupted flow of the developer over the whole plate. I should have feared that with the described "well" dishes there would be apt to be too great a quantity of developer in proportion to the remaining silver solution on plate.—**PHOTOPHIL.**

The heading is an error. It should have been "sensitising" dishes, as the context shows. The wave baths alluded to are made by Mr. R. White, the "Sliplin Manufacturing Compay," West Ealing, W. By following the instructions you should have no difficulty in getting the developer to flow evenly over the plate.

**BROMIDES.**—1. Can you inform me if a bromide print, treated to thorough washing and fixing, is likely to be more permanent than a P.O.P. well fixed and washed? 2. Also, is it possible to harden and prevent blisters by adding some chrome alum only to the plain hypo bath, or to give an extra chrome alum bath instead of pulv. alum?—**S. E.**

1. Certainly the bromides are more permanent. 2. Sulphite of soda should be used as well as chrome alum in a hardening fixing bath. A suitable formula is that on page 964 of the "Almanac," which is not much too strong for bromide prints.

**G. S.**—We suggest that plates require a little more bromide in the developer to keep them quite bright. A plate which develops quickly, as these do, often needs a little extra bromide. Developer which is above the normal 60 temperature, will also give rise to flatness.

**ENLARGEMENTS FROM HARD NEGATIVES.**—To obtain a soft bromide print from a hard negative, the practical way is, as I believe, to give a liberal exposure and diluted developer, and the colour of the enlargement so made is either a pale grey or greenish. Could the above colours be altered to an improved black and white without seriously losing the gradation of the print, and if so, please state in your paper how?—**B. AND C.**

It is difficult to get a good black when using a weak developer; but the best results in our experience are obtained with a hydroquinone developer, or, better, hydroquinone-eikonogen, as follows:—

A. Hydroquinone .....	40 grs.
Eikonogen .....	120 grs.
Soda sulphite .....	480 grs.
Citric acid .....	20 grs.
Water .....	20 ozs.
B. Soda carbonate cryst. ....	60 grs.
Caustic soda .....	50 grs.
Potass bromide .....	5 grs.
Water .....	20 ozs.

Use, A, 1 oz.; B, 1 oz.; water, 2 ozs.

An unpleasant tone is often improved by a short immersion in a toning bath of:—

Gold chloride .....	1 gr.
Soda acetate .....	20 grs.
Water .....	5 ozs.

Or by placing in:—

Potass bichromate .....	10 grs.
Hydrochloric acid .....	5 minims.
Water .....	1 oz.

And re-developing with amidol.

A preliminary weak bath of bichromate (10 grs. per 20 ozs.) applied for a minute or two before development will soften the

print, but the process requires some little practice. A brief note should be given to the print between the bichromate and developer, and the former should not be allowed to act for longer than the prescribed time, two to three minutes.

**ERRATUM.**—An error occurred in one paragraph of the article "Wet Collodion" of last week. Ether "of 820" should be "of 720."

**CIRCULATING LECTURES.**—Messrs. C. P. Goerz announce that they have several new illustrated lectures available for loan to photographic societies, for which they are now booking dates. Full particulars may be obtained on application to the above firm at 1, Holborn Circus, London, E.C.

**THE BUSINESS OF T. Naylor and Sons**, manufacturers of photographic apparatus, has been purchased by Mr. Edgar Scamell, from July 26, and will in future be carried on by him at No. 4, Hanway Street Works, Hanway Street, W., instead of at No. 13 as formerly. The old name of the firm will be retained.

**SCOTTISH SCENERY.**—A book of views typical of Scottish scenery which the descriptive letterpress is printed in both English and Esperanto, is issued by Messrs. Higgin and Co., of Rothesay, in commemoration of the third Esperanto Congress which is now being held at Cambridge, with a view to providing with an intelligible guidebook those who speak this neutral international language. The illustrations are from photographs by Valentine and Sons, of Edinburgh, and the whole forms an interesting souvenir of the places treated in its pages. Copies may be obtained from the publishers, Messrs. Higgin and Co., Rothesay, Scotland, price 6d. each, by post 7d.

**THE THORNTON-PICKARD ANNUAL COMPETITION.**—This competition, which, unlike many others, is an annual event, presents a feature this year in the shape of a special class for enlargements. Cash prizes to the amount of £100 are offered for pictures taken with the Thornton-Pickard cameras and shutters, in some cases the negative also being required. There are seven classes, embracing all kinds of work, and the entries will be judged by the directors and officers of the Thornton-Pickard Manufacturing Company, Ltd., whose decision will, in all cases, be final. Entries close October 1st. Entry forms and full particulars will be sent free on application to the firm at the above address.

**THE "RAJAR" CAMERA**, offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to W. James, Esq., Meadowside, Truro, having been judged the best received during July. The paper on which the print was made was purchased from Mr. E. C. Argall, 9, High Cross, Truro.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—The secretarial duties in connection with the above association are now carried out by Mr. Ernest Human, 43, Whitta Road, Manor Park, Essex.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Two German workers have recorded their experience with ozobrome. It reduces the strength of the pigmenting solution when working on flat originals; another finds collodion prints excellent in bromide work. (P. 634.)

A new flash-powder of very great photographic activity has been made out by Dr. Novak, of Vienna. Comparative measurements of the new mixture and of others are given on page 631.

We reproduce the circular of a firm making a specialty of "speculative outdoor photography." (P. 630.)

Several high-speed photographs of motor-cars are said to be appearing in the American press. (P. 629.)

Mr. Welborne Piper has worked out a method of using bromides in oil printing. (P. 643.)

The Brothers Kearlton demonstrated last week the success of their work in cinematographing timid birds at close quarters. (P. 630.)

Mr. Frank Bishop has retired from an active share in Marion and Co., Ltd. Mr. Gerald Bishop is now managing director. (P. 646.)

Mr. B. J. Edwards is no longer connected with the firm of B. J. Edwards and Co. Mr. E. J. Wall, F.R.P.S., is now technical manager. (P. 641.)

The further hearing of the Chertsey canvassing case is reported on page 645.

Some hints on "Studio Construction" appear on page 635.

Anastigmat lenses, cinematography in colours, mountants, and photographic apparatus are among the patents of the week. (P. 641.)

We give some further notes as to the selection of a view-angle in other reference to Mr. Anderson's article of last week. (P. 630.)

M. Lumière and Seyewetz have recorded the results of experiments on the loss of sensitiveness in plates on being wetted. In general it is slight, though varying with different plates. (P. 632.)

A popular account of the manufacture of the modern anastigmat commences on page 638.

## EX CATHEDRA.

### A Word Wanted.

The receipt of a booklet entitled "Screens and Safe-lights" from Messrs. Wratten and Wainwright, to which we refer on another page, is a reminder of the want of a word to indicate the light-filter used in the dark-room lamp. "Screen" and "light-filter" itself have been so much employed in connection with the filtration of light which reaches the orthochromatic plate at the time of exposure that these words may very well be retained for this signification. But "safe-light" is self-explanatory, and though it may be a practical misnomer at times, it will at any rate be an unmistakable term, and likely to be of service in the constantly greater use which is being made of light-filters of all kinds.

\* \* \*

### A New Flash Powder.

The paper by Dr. Novak, which we translate on another page, contains, it will be seen, particulars of a new flash-light mixture which the measurements show to be in advance of any other formula in the production of a highly photographically active flash. The new cadmium-magnesium mixture is closely approached by that of thorium and magnesium, obtainable commercially as the "Agfa" powder. This latter, according to Dr. Novak's measurements, is but very little behind the newly recommended compound, whilst it has a greater speed of combustion. The figures in the table are instructive, as showing the great differences which exist between flash-powders of the various formulæ, although the list might well be made complete by the addition of a perchlorate mixture, and of the mixture of potassium chlorate, antimony sulphide, and magnesium, which has long been used as a safe if rather smoky powder. The author points out that the danger of spontaneous combustion which exists in the case of a cadmium-nitrate powder containing a trace of acid may be completely obviated by preparing a nitrate containing a proportion of basic salt, the retention of free acid being then chemically impossible.

\* \* \*

### Faked Motoring Photographs.

Mr. C. H. Claudy, in our Philadelphia contemporary the "Camera," calls attention to the photographs which have appeared in the American motor press, in which some suggestion of high speed has been obtained by purposely distorting the photograph of a stationary motor, so as to imitate the result of using a narrow-slit focal-plane shutter at a high speed on a rapidly moving object. The results of this faking process, as the writer points out, are easily recognisable from the fact that the background, if allowed to remain in the photograph, also suffers the same distortion. Usually, too, anachronisms in the

unsharpness of the alleged moving parts of the car are to be seen in these faked pictures of a stationary car. In one particular instance a car, in a photograph which assumes to be that made with the car at the high speed necessary to give rise to the distortion effects, completely fills a 10 by 8 print, and is critically sharp in some portions. It should not be difficult for a non-technical editor to distinguish between the illegitimate and genuine photographs.

\* \* \*

**Nature Cine-matography.** The small company of journalistic and other friends of the brothers Kearton which assembled at the Institute of Journalists last Friday afternoon witnessed a marvellous demonstration of the success which has crowned the endeavours of the Keartons to apply the cinematograph to the record of the life of their timid bird subjects. Having done all that is humanly possible in the way of ordinary photography, the use of the cinematograph at close quarters possessed every element of difficulty which could be put in the path of the naturalist-photographer. How the Keartons have silenced the working of the cinematographic camera so as to be able to use it within a few feet of their sitters is a matter which they leave to the conjectures of their audience, but that they have succeeded beyond their own hopes was evident from the realistic series of films which were projected on the screen. No doubt the methods of field craft which have inspired the property cow and tree have been employed to isolate the taking instrument in a sound-proof receptacle, but however that may be—we are merely guessing—the fact remains that the lecture audiences of the country have now the opportunity of listening to Mr. Kearton's lectures with the accompaniment of a form of illustration beyond which it is impossible to go very much further in the presentation of reality. We hope this triumph of photography will meet with a degree of appreciation equivalent to the immense pains which must have been bestowed upon it.

\* \* \*

#### Invitation Sittings for the Masses.

The example of the society photographer who draws business his way by the method of offering a sitting for nothing has been followed in numberless ways in humbler walks of the profession, but we have rarely seen an announcement so frank as that of a firm in the North of London, which has been distributing from house to house a circular letter in these terms:—

DEAR SIR, OR MADAM,—We respectfully wish to call your attention to this class of Photography. We have now added to our Business an experienced staff of Out-door Operators, and all work is guaranteed of the same high-class quality as delivered from our establishment. Our operator will be in your neighbourhood within two days from the receipt of this circular. We would wish you and friends to be in the foreground of Photograph when taken, so as to give the Picture the desired effect. We do not make any charge whatever for taking the Photograph. We do not require any cash deposits. We trust you; and should the Proof Photograph when submitted to you prove to your satisfaction, we shall be pleased to execute your esteemed orders.

Accompanying this document was an envelope marked "From Official Department." We have nothing to say about the bona-fides of the firm responsible for these overtures. For all we know the business is a perfectly genuine one; in fact, we can only conclude, from the method of conducting it, that it is a reputable piece of business enterprise. Yet we cannot help feeling that such a state of things is lamentable, and repulsive to photographers struggling to follow their craft in the dignified but, we fear, hopelessly old-fashioned way of ten years ago. This "speculative outdoor photography," as its

exponents themselves refer to it, is still another example of the cleavage of the photographers at a middle point into two classes—those putting good work and a certain degree of business restraint before all else, and those who put these matters from them. The middle-class photographer to his own undoing, is left like Kipling's "Tomlinson" not good enough for one or bad enough for the other.

\* \* \*

#### Patent Office Fees.

Those who read the reports of the proceedings in Parliament are fully aware that a new Patents Act has been under discussion for some little time past. One day last week, in a printed reply to Mr. Barnes, Mr. Lloyd George, the President of the Board of Trade, stated that the Patent Office fees have yielded a good profit of late years. Yet he could not see his way to reduce them, in view of the increase in the office expenses. He added that it would not be to the interest of the poor inventor to substitute for the present fees those chargeable in the United States, as that would benefit the comparatively small number of successful inventors at the expense of the others. In America the fees amount to £7, the patent remaining in force for seventeen years, whilst in the United Kingdom the fees total up to £5 at the end of the fourth year. However, we may add that for the full period the fees amount to something like £100. In the reply above quoted, it is mentioned that only 4 per cent. of British patents remain in force for the full term of fourteen years. If this estimate applies to patents for all inventions taken in this country, it is pretty clear that the average, if taken in connection with photography, would be still less than that. Comparatively few of the completed photographic patents have the fifth year's renewal fee paid upon them; indeed, a very large proportion of the applications for patents published in our columns weekly never go beyond the provisional stage. It appears to be the habit of many persons, when they have a new idea, or what they imagine to be new, to rush to the Patent Office and lodge an application for a patent, without duly considering if it is likely to bring them anything in return for even that small outlay. In very many cases the return is nil.

#### VIEW-ANGLE AND FOCAL LENGTH.

We are very pleased to see that our note of July 26 on "Long v. Short Focus Lenses" has elicited an approving and very interesting article from Mr. A. J. Anderson; there is, however, a point of some importance that has not been touched upon either by Mr. Anderson or ourselves, that is, the reason why the ideal view-angle is so small. Art does not acknowledge any laws that have no scientific basis, or, as some would perhaps rather say, no logical foundation; hence, if it is true that a ten-inch lens includes an ideal picture angle on a quarter-plate, there must be some reason for it. There is, in fact, a very simple and sound reason. Such a view-angle includes about 23 deg., and that is just about the angle that we can command with our two eyes without turning the head and without conscious effort. In studying pictures, every one instinctively adopts the position from which he can see the whole with the smallest possible trouble. If the whole picture cannot be taken in, in what people call "one glance," it is seen more or less at a disadvantage—very much at a disadvantage if the picture happens to have a very simple theme, for turning or moving the head practically cuts up the picture into bits, whereas one wants to see it as a whole. As a matter of fact, an angle of 20 deg. is about the ideal, while the maximum

possible angle is about 28 deg. These are the actual picture angles—that is, the angles subtended by the horizontal width of the picture. Taking the width of a quarter-plate picture as 4 in., a 10-in. lens subtends an angle of 28 deg., an 8-in. lens an angle of 28 deg., and an 11½-in. lens an angle of 20 deg. The last is therefore the best angle, while 10 in. is a very good average focal length, and 8 in. is really the minimum that should be used. For ourselves, we use a long-focus lens whenever possible, but on a snap-shooting expedition we prefer a 5-in. lens. Subsequent enlargement, for the simple reason that with that lens we can deal with any subject that presents itself, whereas, as Mr. Anderson admits, a long-focus lens is not always convenient. It is not possible to take every subject at just the ideal angle, and a wide angle is at times desirable for other than pictorial reasons.

It is just possible that some may conclude from what has been said that a narrow picture angle is essential in a picture that claims to be a picture. This is far from being the case. There are subjects with which wider angles are necessary for purely pictorial reasons. A painter naturally considers 60 deg. to be about the limit, but he employs such a wide angle as this for exceptional effects, and such subjects for the most part are quite unsuitable to photography. From the nature of photography it is impossible to deal in any satisfactory manner with complex subjects. Simplicity of subject is the key to success in pictorial photography, while a crowded subject is altogether unmanageable. On the other hand, the photographer can deal most successfully with complex subjects if the photographer is foolish to expose a plate upon a subject of which the desirable picture angle varies with the subject, wide angles generally going with complexity and narrow angles with simplicity. Therefore, the photographer is naturally led down to narrow angles. The exception to this is to be found in the case of architecture. Here the architect is the artist, his adjustment of the parts of the complex whole is perfected, and neither painter nor photographer is at liberty to interfere with it, hence both

are on the same footing so far as selection of angle is concerned.

Another point touched on in Mr. Anderson's article is the use of the view-finder. If one is going to use the whole of the picture included on the plate, an accurate finder is very necessary, otherwise some important part of the subject is sure to be cut off. In such a case the reflex camera scores beyond all others. But if it is intended to utilise a portion of the plate one need only use the finder to centre the view, and the boundaries of the view can be adjusted after, upon the negative or print. As regards the composition of the view, it always appears to us to be a mistake to settle this with the aid of the image seen in finder or on the ground glass. In photography, composition depends entirely upon the selection of the point of view, and in our opinion it is not only more instructive, but better in all respects to settle this by direct observation of the subject. We prefer to be without a camera altogether when studying points of view, and when the various most likely points have been selected we only use the finder or the focussing-screen to see how the subject will fill the plate, or the portion of it that we intend to use. For this purpose a simple rectangular frame, such as that described by Mr. Anderson, is not only as satisfactory as, but in our opinion superior to, any other form of finder. Hand-camerists would probably produce a greater number of likely pictures if they paid less attention to the finder picture and more to the subject itself, and if they used the finder simply for the purpose of centring the view and ensuring that the whole of it is well within the limits of the plate. If enlargement is to be resorted to, the actual size of the image (within reasonable limits) is of little importance; but as a rule we fear the majority of people pay more attention to this relatively unimportant matter than to anything else. They use the finder to see if they can get nearer the object and secure a larger image, whereas they ought rather to use it to see if they can get further away without making the scale too small.

## FLASHLIGHT MIXTURES.

The following report of experiments made in the Vienna Institute of Graphic Arts by Dr. Novak; to whom photographers are indebted for several similar investigations, may be studied by makers of these compounds rather than by the amateur user, in whose hands the manufacture of such products is attended with no little risk.—Eds. "B.J."]

Points require to be taken into consideration in producing a satisfactory flashlight mixture:—

The amount of light, possessing photographic activity, produced.

The rapidity of combustion.

The amount of smoke produced.

Ordinary practical tests suffice to show the great differences that exist between the various mixtures in respect of these properties. The author's object, therefore, has been to employ methods of greater accuracy in examining various mixtures as regards their photographic activity and speed of combustion, in order to provide a more exact numerical comparison of the preparations.

The photographic intensity of the flash was determined with a tube photometer<sup>1</sup>, in which ordinary gelatino-bromide

plates were exposed. The measurements were thus obtained in candle-meter seconds<sup>2</sup> (H.m.s.), the Hefner amyl-acetate lamp being taken as a unit.

Three ground-glass screens were fixed in front of the sensitometer: the flash was fired at six metres distance by an electric igniter, and each sample examined contained 1 gm. of magnesium.

The measurement of the time of combustion was done with Rheden's apparatus<sup>3</sup>.

Regarding the preparation of the flashlight, it may be noted that the separate substances were finely powdered singly and mixed with the magnesium powder on a piece of glazed paper. Such a precaution is, of course, necessary in all cases on account of the explosion of the mixture which may take place through rubbing or shock.

<sup>1</sup> A candle-meter-second is the chemical effect of a Hefner amyl-acetate lamp in one second at one meter distance.

<sup>2</sup> Photographische Korrespondenz, 1903, p. 115.

<sup>3</sup> Photographische Korrespondenz, 1903, p. 428.

The following table gives the results of the determinations. It should be noted that the mixtures of magnesium with zinc nitrate and with cadmium nitrate have not been previously examined:—

Mixed with 1 gm. (15 grs.) of magnesium powder.	Relative photographic intensity on gelatino-bromide of silver.	Time of combustion in seconds.
	H.M.S.	
Potass permanganate ( $\frac{1}{2}$ gm.) .....	173,000 .....	·12
Potass nitrate 1 gm. ....	36,000 .....	·07
Barium nitrate 1 gm. ....	60,000 .....	·07
Strontium nitrate 1 gm. ....	84,000 .....	·105
Thorium nitrate 1 gm. ....	281,000 .....	·220
" " $\frac{1}{2}$ gm. ..	332,000 .....	·230
" " $\frac{1}{4}$ gm. ..	358,000 .....	·24
Zirkon nitrate 1 gm. ....	237,000 .....	·24
Ceric nitrate 1 gm. ....	173,000 .....	} Burns slowly in about 1 sec.
Zinc nitrate 1 gm. ....	173,000 .....	
" " $\frac{1}{2}$ gm. ....	282,000 .....	·250
Cadmium nitrate, slightly basic, 1 gm. ....	399,000 .....	·270
Molybdic acid 1 gm. ....	20,000 .....	·300
Ammonium molybdate 1 gm. ....	86,000 .....	} In about 1 sec.

Perfectly dry materials were used for all the preparations. In the case of one mixture, that with the cadmium nitrate, it was noticed that a trace of nitrous or nitric acid in the preparation rendered the mixture liable to spontaneous combustion; which took place usually a few minutes after making the mixture. If, however, a few drops of soda solution are added to that of the cadmium nitrate, so as to produce a slight precipitate, the result, after evaporation, was a mixture which is slightly basic, and gives rise to no spontaneous combustion.

Of the various mixtures, that which gave the greatest photographic intensity is that containing cadmium nitrate. Next in order comes that with thorium nitrate. It is further seen

from the table that the light obtainable varies with the proportion of thorium nitrate, the most favourable proportion being

Thorium nitrate .....	1 part.
Magnesium .....	2 parts.

Ceric nitrate is useless as an oxidant in flash powders, as too slow in burning. It may, however, be useful as a time on account of its high development of useful light. The combustion could be easily prolonged still further by the introduction of suitable inert bodies. The author hopes to report the results of experiments in this direction.

A very luminous flash is obtained from the mixture of zinc nitrate ( $\frac{1}{2}$  part) and magnesium (1 part); but the mixture containing molybdic acid and ammonium molybdate has no practical value.

In reference to the time of combustion, the compounds of potassium or barium nitrate burn the quickest. The time of combustion of the cadmium and thorium powders is about four times as great, but practical tests have shown that the latter speed is fully sufficient for successful exposures, while the mixtures have the great advantage of providing nine times the "photographic" light of those with potassium nitrate.

The greater or less development of "smoke," so important in practice, was found to run pretty much according to the amount of light that the greater the light the less the smoke. The mixtures of potassium nitrate gave the greatest amount of smoke, and those with thorium or cadmium the least.

The properties of the mixture of magnesium and basic cadmium nitrate (1:1) have not been previously published, but are worthy of notice on account of their favourable character from the practical standpoint—that is to say, great luminous intensity and very little smoke.

It should be mentioned in conclusion that the light emitted by the cadmium-magnesium mixture produces a continuous spectrum in addition to the familiar magnesium lines.

FRANZ NOVA

## ON THE ACTION OF WATER AND OF DEVELOPING SOLUTIONS ON THE SENSITIVENESS OF GELATINO-BROMIDE PLATES.

It has been noticed that plates impregnated with water or developing solutions have their sensitiveness to light diminished in proportion varying with the particular plate. This fall in sensitiveness can be produced by moistening the plates with the liquids as well as by immersion of the plates during exposure. We set ourselves to examine this phenomenon in order to discover what practical results it would lead to as regards the better illumination of the dark-room, as well as to ascertain the effect of the hydrometric condition of the air on the sensitiveness of photographic plates. Two series of tests were made, one dealing with the general sensitiveness of the plates, and the other with their sensitiveness to different parts of the spectrum. An electric incandescent lamp was used in the first, daylight in the second. The experiments were carried out with the following plates:—

Rapid Emulsions.—Lumière "blue label."  
Lumière Ortho A.  
Lumière Ortho B.  
Lumière panchromatic.  
X rose label.  
Y American.

Slow Emulsion.—Lumière red label.

### The Effect on General Sensitiveness.

The influence of the temperature of the developer and of the time of development on the experiments was eliminated by exposing at the same time as each plate was examined a dry check plate coated with the same emulsion. This exposure was made in one and the same vessel divided into two compartments, one of which contained the dry check plate, and the other the plate immersed in the water or the developer. The sides of the vessel thus holding the two plates were opaque, and the upper part could be closed entirely or partly by means of a shutter, by means of which a series of increasing exposures could be made by exposing successively the different portions of the plate. The plate was thus divided into a number of bands, one of which had not been exposed at all, whilst the others had received exposures increasing in the progression, 1, 2, 3, etc.

Each brand of plate was examined as to its behaviour in the following liquids:—

A.—1. Immersion in water only followed by normal development in diamidophenol.

2. Immersion in diamidophenol developer, followed by development in the same solution.

—1. Immersion in plain water, followed by development in roquinone and a carbonate.

Immersion in hydroquinone-carbonate developer, followed development in the same solution.

—1. Immersion in plain water, followed by development in  $\alpha$ -acetone.

Immersion in the pyro-acetone developer, followed by development in the same solution.

In a second series of experiments the plates, instead of being exposed under the layer of liquid, were simply moistened with brush soaked in water or the solution.

The results of these two series of tests were identical. They were such that in the case of using an incandescent electric lamp as illuminant, the loss of sensitiveness is practically the same both water and developing solutions—that is to say, that the loss is due to the absorption of light by the layer of liquid covering the plate.

The Sigma plates and the blue label plates suffered an appreciable loss of sensitiveness. The Ortho A plates, the slow plates (label), sustained only a weak reduction of their sensitiveness, whilst the Ortho B plates and the panchromatics appeared to retain practically all their sensitiveness.

The phenomenon is most marked in the case of the Sigma plates, the sensitiveness of which became one-quarter to one-fifth that of the unwetted plates. This fact has allowed of our developing without fog plates of the Sigma brand, which had been normally exposed by immersing them for a few seconds in water. The dark-room was lighted by a yellow incandescent lamp of 16 candle-power placed at a distance of three yards from the dish. The plate was examined twice, the first time two minutes, and the second time three minutes, after the commencement of development. Blue label plates exposed under the same conditions, as well as all the other plates, excepting those of slow speed, gave a very appreciable fog.

#### Influence of the Quantity of Absorbed Water on the Loss of Sensitiveness.

The maximum fall in sensitiveness (due to moistening with water) taking place in the case of the Sigma plates, we endeavored to determine in the case of these plates:—

1. The quantity of water necessary for the loss in sensitiveness to begin to be appreciable.

2. The quantity of water needed to produce the maximum loss in sensitiveness.

For this purpose we exposed Sigma plates under a bell in an atmosphere saturated with moisture, and compared their sensitiveness with check plates which had been allowed to remain in an atmosphere for times varying from two minutes to five hours. We found that at a temperature of about 60 deg. Fahr. the loss in sensitiveness became appreciable after about half an hour in the bell, and reached a maximum (one-quarter to one-fifth the original sensitiveness) when the action of the damp air had been continued for about four hours. On determining the relative weights of water which a plate absorbs after a time of half an hour and of four hours in an atmosphere saturated with moisture the following figures were obtained:—

Water in a plate 13 by 18 cm. ....	128 gm.
Water in a 13 by 18 plate after half an hour in atmosphere saturated with water .....	1,334 gm.
Water in a 13 by 18 plate after four hours in atmosphere saturated with water .....	288 gm.

#### The Influence of Dryness on Sensitiveness.

It seemed advisable to determine whether part of the loss of sensitiveness produced by absorption of moisture is permanent, or if on desiccation in the air the plate regains its original sensitiveness; also whether drying at 212 deg. Fahr. or by prolonged exposure over sulphuric acid produces any increase of sensitiveness. In the first case the plate regained its original sensitive-

ness. In the second case no increase of sensitiveness above the normal could be noticed.

#### Experiments on Orthochromatic Sensitiveness.

In these experiments the solar spectrum was photographed in a spectrograph, and the various plates used, as in the previous series of tests. The results of these exposures are contained in the table subjoined. They show that for a given liquid there are, in certain cases, notable differences between the action of white light and that of particular spectral regions.

It will be noticed that variable losses of sensitiveness are obtained with the different developers used to wet the plates when daylight is used, although in the same conditions but using incandescent electric light the differences are very much less.

#### Conclusions.

From the results above described the following conclusions may be drawn:—

1. Gelatino-bromide plates experience a fall in sensitiveness when wetted with water or developer, but regain their initial sensitiveness on drying. They do not, however, assume a greater degree of sensitiveness on complete desiccation.

2. The loss of sensitiveness varies with the plate. It is most marked in the case of the Lumière Sigma plates.

3. The loss of sensitiveness varies, for the same plate, with the different regions of the spectrum to which the plate may be exposed. It is most marked in the green and yellow.

4. The above facts can be advantageously applied in the illumination of the dark-room.

A. AND L. LUMIÈRE.  
A. SEITZETZ.

## CONTROL IN THE OZOBROME PROCESS

(A Paper in "Photographische Korrespondenz.")

THE ozobrome pigmenting solution, as has been mentioned in the many articles on the subject, consists essentially of a mixture of potassium ferricyanide, potassium bromide, and potassium bichromate. The chemical processes which are performed by these chemicals are somewhat as follows:—The ferricyanide acts as a strong oxidising body on the silver image, converting it, in the presence of potassium bromide, into silver bromide, and being itself reduced to potassium ferrocyanide. This latter body undergoes an immediate re-oxidation to ferricyanide by means of the bichromate, which is thereby reduced to chromium oxide. This latter then acts as a hardener of the pigment film in a method similar to that which occurs in the carbon process. There is thus formed a certain definite proportion of hardened bichromated and pigmented gelatine according to the quantity of silver in the original bromide print, and it is noteworthy that the strength and gradation of the silver print fixes the final ozobrome result. The latter can, it is true, be varied within certain limits as regards its intensity by the pigment selected; nevertheless, with a special selection of pigment, as is the case in the ozobrome process as commercially offered, the equivalent of the silver print in carbon is obtained.

In general, the ozobrome process is worked by the transfer method on account of the fact that the original bromide print being upon baryta paper, the latter becomes slightly brittle during the various operations, and requires an after-bath of glycerine in order at the end to get the print to lie flat. If, however, specially prepared bromide paper is used in the original instance, there is no necessity whatever to transfer the print, although in this case, as is well known, several carbon duplicates cannot be obtained from the same print.

The development of the ozobrome print takes place just in the same way as that of ordinary carbon copies, the chemical tanning of the gelatine being precisely analogous to that of the light in the carbon process. It is usually well not to exceed the time of immersion in the pigmenting solution recommended in the directions, namely, two minutes. This time is found fully sufficient for even the most vigorous bromide prints. A longer time gives somewhat stronger ozobromes, but a period of immersion of three to four minutes is liable to cause fog or partial insolubility of the gelatine film, with the result that extremely hot water is required for the development. A shorter time of immersion than two minutes is equally inadvisable, as the complete decomposition of the silver in the print does not then take place, and therefore the shadows (particularly) of the ozobrome suffer. It is obvious that a certain proportion of ferricyanide is necessary for the conversion of the silver image, and since the solution is only available through absorption of it by the pigment paper, it is easy to see that with too short a time of immersion the bleaching process may not be complete in the case of prints of more than the usual vigour. The result of this would be that the shadows appear flat in contrast to the half-tones, in consequence of the tanning of the film not having been proportional to the amount of silver in the bromide. Curling of the pigment paper on immersion in the ozobrome solution can be avoided by softening the paper for one minute, not longer, in water at 60 deg. F., and then, after allowing the water to drain off, immersing in the ozobrome solution. It is well if this procedure be followed to use a rather stronger ozobrome solution for the same time of immersion, or to immerse for about half a minute longer. As a rule, it will be found that in the case of pigment paper which has been packed flat there will be no need to take precautions as to curling, provided that the paper has not been kept in too

dry a place. Previous softening has the result that the pigment film does not adhere so well to the support, and on development in warm water may very easily become detached.

It is important to ensure the pigment paper being brought quickly into contact with the silver image, while the latter lies on a glass plate, without inclusion of air-bells. As the chemical action of the bath takes place at once on the wet bromide print it is easy to see that veil and dark or light patches will be the result of working too slowly, and if the pigment image moves after having been squeegeed to the bromide, double outlines are the natural consequence. In some directions which have been given by various writers on the ozobrome process, it has been suggested that the two prints should be laid together under water, the pigment tissue having been previously immersed in the ozobrome solution, and that they should be brought into contact below the liquid and then removed and squeegeed. The writer's experience, however, is that the method suggested above is preferable, as it avoids irregularities due to the diffusion of the ozobrome bath from the pigment film.

The strength of the bath and the time of immersion are very important points in making ozobrome prints. It may be taken that two to three minutes is a normal time of immersion in the standard bath—i.e., five times diluted—recommended for the process. The strongest pigmenting solution which can be usefully employed is 1 to 3, and the weakest 1 to 6, these figures representing the proportion of water added to the commercial solution. Pigment prints of great softness are obtained by using stronger solutions for the normal time. On adopting a longer time of bathing, the prints become still softer, but fog frequently occurs, and the development is rendered more difficult owing to partial insolubilisation of the pigment film, making the use of hotter water necessary. Greater contrasts and greater clearness of the high-lights are obtained by using a more dilute solution for the normal time.

The two extremes concentrated solution and long immersion and dilute solution and short immersion should be avoided as far as possible.

It may be well to summarise those variations which can be made in the practice of the ozobrome process in the following short table:—

Silver Prints.*	Strength of the Ozobrome Solution, temperature 60 deg. F.	Time of Immersion
Strong, tending to hard ... ..	1:3 .....	2 (1½)
Too strong, but with good half-tones ... ..	1:5 .....	3 (2)
Normal, i.e., with good gradation and great strength... ..	1:5 .....	2½ to 3 (2)
Somewhat flat, lacking strength in the shadows ... ..	1:6 .....	4 to 5 (3-4)

NOTE.—It is assumed that the pigment tissue is softened by immersion for one minute in water before placing in the ozobrome solution. If immersed dry into the solution, the shorter times of immersion given in parentheses in column 3 should be used.

A time of immersion of 1½ minutes can obviously scarcely be given in the case of a very dry pigment paper which has not been previously softened, and attention should be paid in working the process to the proper state of the pigment paper before immersion. In the case of pigment tissue previously softened in water it is possible to adopt a time of immersion of any desired degree of brevity.

\* Gelatino-chloride and chloro-bromide prints give as a rule softer ozobromes than bromides of similar strength; but it should be remembered that any print the image of which consists of metallic silver may be used for the ozobrome process. The vehicle of the silver print appears also to have little influence on the preparation of ozobromes, since a print made on "Rotary" matt collodion paper, washed, fixed, and again washed but not toned, gives entirely good results as the original for ozobromes.

In the case of ozobromes which are treated in a strong solution, 1 in 3 of the pigmenting bath, and are given a fairly long time of immersion—e.g., three minutes—but nevertheless do not come out with sufficiently soft contrasts, it is advisable to first immerse the silver print itself in water for a few minutes, soak it in a 1 per cent. solution of alum for two minutes, allow the latter to drain completely away from the print, and then bring the print into contact in the usual way, the pigment print having been immersed for two minutes in a 1 to 5 ozobrome bath in this way, prints of excellent clearness and softness are obtained. Similar results may be achieved by addition to a 1 to 6 ozobrome solution of a little alum solution. About 5 c.c.s of 10 per cent. solution of alum is the correct quantity to add to about 100 c.c.s. of the bath. These methods of control may prove useful in those cases where previous treatment or control of the silver prints cannot be undertaken.

Slight veil or fog on the ozobrome prints can be dispersed by rubbing water over them or throwing it over the prints with the hand or with a wad of cotton wool lightly applied with pressure to the prints. More pronounced fog results, as above observed, from too long immersion in solutions of too great strength. The addition of alum makes the pigmented film, especially that on the surface, partially insoluble, whereby a slight veil is formed even in the highest lights. It should be borne in mind that a very weak veil of this kind should always be present, just as it should be in ordinary carbon printing. The tanning action of the alum exerted not only on the pigment film, but also on the bromide print, prevents great penetration of the ozobrome solution, with the result that a print in similar relief, and therefore of greater softness, is the result.

The time of contact between two prints is directly dependent

upon the hardening (aluming) of the silver print. I have found that even for very strongly hardened prints fifteen minutes is fully sufficient; it is only necessary to see that the solution does not evaporate from the paper, and if the latter and the pigment tissue are placed between two glasses, it may be left over night and perfect prints afterwards developed. In the case of prints which have hardened by age it is frequently found that the half-tones come away. In such cases, it is well to unhardened the prints in a bath of 3 per cent. acetic acid, afterwards washing thoroughly from ten to fifteen minutes, and then hardening afresh with 3 per cent. alum solution, with a further washing of fifteen minutes; such prints can be placed in water and brought into contact with the "ozobromed" pigment tissue.

In carrying out the above unhardening process, it is advisable to go over the print with a soft brush or tuft of cotton wool to remove air-bells in each stage; without this the latter are apt to appear in the finished print in the form of white spots.

In the case of ozobromes for which bromide prints are being specially made, it may be sometimes convenient to remember that the ozobrome can be prepared before the print has been fixed. In this case the developed print is rinsed, hardened for ten minutes in alum solution, and washed for ten minutes without access of light. It is then placed, according to the ordinary methods, in contact with the pigment paper and developed in warm water. In working by the non-transfer process, fixation should be given in any case in order to remove the bleached bromide image, and therefore the whole of the silver bromide is removed from the print. This method, which can be used also in the cases of collodio and gelatine printing-out papers, is often advantageous in preparing ozobromes.

OTTO SIEBERT.

#### OZOBROMES FROM COLLODION PRINTS.

The above notes of Herr Siebert may be supplemented by the following from the current issue of the "Photographische Mitteilungen," describing the writer's experience in the use of collodion

prints as originals in the ozobrome process.]

In order to be successful in the use of collodio-chloride prints as originals for the preparation of ozobromes, the collodion paper could be printed somewhat deeper than usual and the free silver thoroughly washed out. The prints should not be toned, nor for the same reason should the self-toning papers be employed. The prints are simply fixed, again washed, and are then ready for use in the process. In fact, it is not necessary to fix the prints; they may be used in the pigmenting process as soon as washed. A dilution of the purchased ozobrome solution, with five times its volume of water and a time of immersion of the pigment tissue of two minutes therein, will be found about the correct standards to employ when

working from collodion prints. The time of contact with the pigment tissue may average about twenty minutes. Equally good results may be obtained on glossy and matt paper, but it is advisable to use a safe edge in order to secure the adhesion of the pigment print to the collodion surface when the non-transfer form of the process is worked.

Aristo, albumen, and casein papers have not proved so satisfactory as originals for ozobromes. They are capable of good results, but at times the reproductions are not satisfactory. The irregularity probably arises from the different degrees of resistance of the films of these papers to the penetration of the ozobrome solution.

FRITZ WENZEL.

## HINTS ON STUDIO CONSTRUCTION.

Those who regularly read, as I do, the replies to queries given in the "Answers to Correspondents" column of the "British Journal" will have noticed the number of questions that relate to the construction of studios, the kind of blinds best for them, the colour the studio should be painted inside, etc. Some practical hints, therefore, on the subject by an old hand in portrait photography may possibly be of use to others younger in photography. Apparently many of the queries emanate from those who have had but limited practical experience in the profession; they cannot adapt themselves to circumstances without aid, or they would not require enlightening on the simple matters to which their queries relate.

Judging from some of the queries and from advertisements of businesses for sale, in which a studio with a north light is made a feature of, it would seem that the idea is somewhat prevalent with many that it is only in the studio with a north light that good pictures can be taken. If that is the case, no greater fallacy exists. The only advantage I can conceive in a studio with a north aspect is that the light is generally more uniform throughout the day

than in any other. For that reason inexperienced or unskilful workers may be enabled to produce better results than they would otherwise do. With a northern aspect also the sun gives less trouble than with others, but experienced hands know quite well how to deal with that as circumstances arise. I have even heard of very eligible premises, as regards business, being rejected for others in a far less suitable place, merely because a studio with a north light could not be erected there.

The aspect of the studio is quite of secondary importance as compared with the business position. The excellence of the work depends entirely upon the photographer who works it. During my quarter of a century in portrait photography, a good part of which was in the collodion days, I have worked in studios with aspects of nearly all the points of the compass, except the north. I never had the experience of working with a north light. The nearest approach to it has been north-east and north-west. Once I worked for a time in one with a due south light, and I may say that, amongst what I consider the best pictures I have produced, were those taken in the south-lit

studio. The light was very variable, it is true, but that is of little moment to anyone who understands his business.

### Studio Types.

*En passant*, I may remark that the late Mr. Valentine Blanchard, as well as the late Mr. Adam Salamon, whose portraits created such a *furor* for the effects in their lighting about the early 'seventies, preferred a south light to work in, and had their studios constructed with a south aspect. One of the advantages of a south light is the great variety in lighting that can be obtained with more ease than in many others. The light also is stronger, and enables shorter exposures to be given, no mean advantage in winter. Incidentally, it may be mentioned how the studio above referred to in which I worked was built. It was of the lean-to form. The side light, which was fairly high, was glazed with ground glass, the roof with plain glass. This was fitted with two sets of blinds, on spring rollers; those next the glass were white, and the others black. The side was fitted with black curtains running on rods. With this simple arrangement I obtained pictures with great variety in the lighting, and they gave great satisfaction to the sitters.

For two years my work was done in a studio with an all-top light; there was no light at all below 9ft. from the floor, yet satisfactory portraits were obtained in it. Fortunately, the studio, or, rather, room, was large, and by means of reflectors the top light was, to a great extent, converted into a side one. However, this kind of studio is certainly inconvenient, and is by no means to be recommended if circumstances will permit of any other being constructed. In many instances, as in this, the photographer is restricted to certain aspects, and also by restrictions with regard to the Building Acts, also by the by-laws made by local authorities, so that the best has to be made of the existing circumstances. "The coat must be cut according to the cloth."

The most general forms of studio at the present time are the ridge or span roof and the lean-to, and both are good. The former can usually be lighted from both sides, and the latter, of course, from one side only. Hence with the latter, unless both ends of the studio are used for sitters, all must be lighted on the same side. Hence there is a great sameness in the lighting of the portraits. With the span roof it follows that either side light, provided it is not obscured by other buildings, can be used as occasion may require. Two studios in which I worked for some years were of the ridge roof form, and ran north and south, so that the sitter, when placed at the south end, could be lighted with either east or a west light, which was a great convenience. In the earlier part of the day, when the west light could be used, there was no trouble with the sun. Neither was there in the latter portion, when the east light could be employed. Such studios are very convenient to work in, but space and surrounding conditions are not always available.

### The Lean-to Studio.

A very favourite form of studio at the present time is the lean-to form, and, on the whole, if both ends are utilised for the sitters, this is the one to be preferred. For general work it is desirable its length should not be less than 25ft. to 30ft., and its width 13ft. or 14ft. This will permit moderately large groups to be posed, and lenses of fairly long focus being employed, so that good perspective is obtained in the pictures. With short studios the sitters have to be placed very close to the background, and, as a consequence, there is no atmosphere between them. Hence the sitter looks more as if he were stuck on to the background, or even let into it. Short studios also necessitate the use of short focus lenses, so that perspective becomes violent, and the pictures convey the idea of distortion. Most of those who take large heads, where the lens has to be placed 6ft. or 7ft. from the sitter, find that this class of pictures, as a rule, does not give the same satisfaction as do smaller ones taken at a greater distance.

### The Proportions of Glazing.

Here are good proportions for a studio for general work, whether of the lean-to or ridge form. It may be well to say here that it is undesirable to have more glass than is really necessary, as this tends to make the studio unduly hot in summer and unnecessarily cold in winter. We will consider one, say, 27ft. long and 14ft. wide. The height of the roof at either end, and 4ft. at the sides may be opaque, solid. The wider the studio the more at the ends may be made opaque, and the narrower, the less. The height from the floor to the eaves may be 8ft. 6in. to 10ft. from the floor, inclusive of about 3ft. of skirting next the floor. This may be glazed with plain glass, or, if the studio is much overlooked, with fluted glass, as that does not obstruct the light, and yet cannot be seen through. The height from the eaves to the ridge may be about 6ft., and that will give a good slope to quickly carry off rain, and thus help in preventing the water finding its way through. A very suitable glass for the roof is what is known as rolled plate. It is thick, obstructs but little light, and is not likely to be damaged by hailstorms. The glazing need not be carried up to the ridge by a couple or three feet, then the roof can be made more easily, and kept, watertight. Also, the blinds or curtains, whichever are used, can be made more easily fixed, so as to exclude light.

The framework of the building is best of iron, as that is not affected by the weather in the same way that wood is, and for this reason the roof can be kept in a watertight condition. On the other point should be kept in mind in designing a studio—namely its ventilation. Ventilators, that can be opened and closed as required, should be placed in the highest part of the studio, and it is also a good plan to have others at the lowest portion, so that a cool current of air can be admitted at the bottom, and the heated air pass out at the top.

WM. MICHELL.

## A TRIUMPH OF RECORD PHOTOGRAPHY.

[The following notes by Mr. E. S. Curtis, of Seattle, U.S.A., which appear in the "Photographie Times," describe a photographic undertaking which is almost without an equal in respect of the time devoted to it and the thoroughness with which the camera has been applied to recording the features of a dying race. It is possible that Mr. Curtis's remarkable Indian pictures will be seen in England.—Eds. "B.J."]

You ask me to tell you something of my work that would be of interest to photographers. I question anything in connection with it or information in regard to it being of much help to my fellow photographer, unless it would be to convince him that his life is one of comparative ease and comfort. To begin with, for every hour given to photography two must be given to the word picture part of this record of the vanishing Indian. True, many of the hours given to the writing are those of the night time, and the light is not a 32 candle power stand lamp, but most likely two or half a dozen tallow candles fastened with their own wax to a scrap of plate or grub box. The everlasting struggle to do the work, do it well and fast, is such that leisure and comfort are lost sight of. To the oft-asked question, "What camera or lens do you use?" I can only reply, "I could not tell to save my soul; it is enough for me to know that I have something that will make pictures and

that it is in working order." And as to chemicals, I have almost forgotten that they are a necessary part of photography. With us it is seven days in a week, twenty-four hours in each day, and thirty-one days in most months. We sleep when we cannot work, and here is one place where we are most particular. Our beds must be as comfortable as human ingenuity can make a camp bed, for while we do rest we want to rest well. Most likely the roof to our apartment is the sky blue dome, but to sleep in the open is real rest.

### An Outfit Weighing one Ton

The field season of 1906 was nine months long, beginning in the mountains of Apacheland, with snow still in sight, and long before the season ended we were snow-bound in the mountainland of the Hawalapai. The field party for the season was, firstly, Justo, our Mexican cook; two helpers, who could best be called ethnologists,

ing the lore, logic, and history of the people, one of whom as my stenographer; and myself, I doing the photography. Being three of us at work, there had to be three interpreters, and, of course, we secured from each group with which we were working. During the season we have worked with fourteen languages and no end of dialects. Our camp equipment, weighing from a hundred pounds to a ton, depending on distance from a source of supplies; in photographic and other equipment there were several cameras, a motion picture machine, phonograph for recording, a typewriter, a trunk of reference books, correspondence files running over a year of business affairs, as, being always on the move, it is necessary to keep up my regular correspondence in connection with the work, its publication and the lectures all from the Tents, bedding, our foods, saddles, cooking outfit, four to six horses, such was the outfit. Some one has to boss the job; usually it falls to me. Everything must be kept on the move that no thing is lost. Teams have to be bought, supplies secured, both country and photographic, arrangements made for getting and sending. On long stretches the whole outfit has to be shipped. At times the nature of the country does not permit of waggon travel, and the train has to be made up and managed, or, perhaps, it is water transportation, boats to be bought or built, and, when secured and loaded, must be handled, be it rough or smooth water, and, withal, the thing that must never be lost sight of, the purpose of the work—its nature and word history of the Indian and his life. But at times the handling of the material side of the work almost causes one to lose sight of art and literature.

#### A Year's Touring of 60,000 Miles.

During the field season of 1905 sixty thousand miles of railroad were used. The totals of 1906 are not yet made up. And come the elements. The rain pours down. What was an arid plain when you made your evening camp is soon a lake. Perhaps in the darkness of the night you have been compelled to gather your camp gear and carry it to higher ground; or, perhaps, it is a fierce storm striking your camp, and if strong enough it will either blow you to the ground or whip them to shreds. And then comes the storm. No horse can travel against it. If *en route*, you turn out your waggon to one side to furnish as much of a wind-break as possible, throw a blanket over your head, and wait for its passing. It may be two hours or it may be ten, and when it is over your equipment is in sorry shape. Nothing can keep it out. Trunks, plate box, plate holders, motion machines, food—everything is sifted full of this fine powdery sand. Hail-storms will come down on you and whip your camp into tatters. At another time it may be the heat, so intense that a furnace seems cool in comparison. I have a keen recollection of a ten-day trip through desert and mountains, when each day the thermometer registered more in the shade, and water was more precious than gold. On the other hand, it may be snowstorms and cold that will lead you to forget that you were ever warm. We have just passed through one. We went into the high mountains with a hunting party of Indians. Soon the snow began to fall, and when it snows in the mountains it does that, and nothing else. When the snow reached our waggon hubs we decided it was time to retreat. The road, hard to find at any time, was lost in the snow. Mountain peaks and land marks were invisible in the falling, drifting, swirling of white. The horses floundered and fell, regained their feet, struggled on, only to give out completely and lay down in the snow. Food ran low, and we had the added misery of hunger along with the bitter cold. At another time a stubborn driver rushed his horse team down a bank and into a fresher torrent, where, in the fragment of a minute, all you could see of that waggon was its top, and a muddy stream for a quarter of a mile was strewn with the wreckage. From a half dozen cameras scarcely one could be fished up out of that wreck, and plates—well, the shortest time to get a new supply was ten days and a trip to cost hundreds of dollars. Another day the pack mule, with my only camera fastened to its back, slipped and rolled down the canyon a mile. The camera was spread out on the mountain side, seeming to be nothing but a piece of canvas. Twelve hours' steady, patient work, and it was patched so it could be used. But such a sight! No camera worker has ever saw anything quite its equal. On the outside it was a mass of ropes, bound and twisted in every direction, to hold it together.

All this has not happened in one season. There have been nine of them, each having its good share, and yet I have not spoken of the people with whom we have to deal. Each tribe or village is like unto no other, but all have their full share of superstition and secretiveness, to say nothing of stubbornness. Each tribe visited is a new situation to be taken up and mastered, and that quickly. Every phase of their life must be noted, and, as far as possible, pictured, and the gathering of this lore, logic, and myth must go hand in hand with the picture making, as, without the knowledge of their life, ceremony, domestic, political, and religious, one cannot do the picture work well.

#### Snowstorm Portraiture.

How do I manage the portraits and the handling of the life? In every way. Conditions cannot be changed. I must fit myself to them. Some of the portraits can be made in my tent, which is a fair sized one, made for photographic work. Many more are made in the open, in the soft light of the morning or the intense glare of the mid-day sun. The subject secured, it matters not the time or conditions. The picture must be made. My fine picture of Alchasa, the Apache chief, was made in the strong light of the mid-day sun, the background a juniper tree. The picture of Red Cloud, the Sioux, was made in strong sunlight, on the open prairie. The particularly fine one of the Jicarilla chief was also made in the strongest glare of open sun, and the background a red blanket. A certain fortunate picture caused the question, "How did you get that beautiful soft effect?" It is easy to answer. The picture was made in a blinding snowstorm, and the falling snow between the lens and the sitter caused the semi foggy effect. The results were satisfactory, but the doing of it exceedingly uncomfortable.

My mood to-night seems to have been to tell of the difficulties and hardships. Do not think that this is the only side of the work. For every hour of misery I could tell you of one of delight, and the most stormy days have had glorious sunsets, and for every negative that is a disappointment there is one which is a joy, and for every page of these trials I could write you countless ones of the beauties of Indian land and Indian life.

You may ask how long the field work will last? When the Navaho does not know the answer he says, "Whooh," which is, perhaps, the only answer. This I do know: that for six years more the work will be driven to the limit of human endurance. After that there will be a little more leisure.

#### A De Luxe Publication.

The Curtis publication of the North American Indian will consist of twenty volumes of text, and bound in with the text of these twenty volumes will be fifteen hundred of the small pictures, each one of the fifteen hundred being a full-page photogravure of the best quality. Several of the photogravures in each volume will be hand-coloured plates of ceremonial subjects. The book in size will be a page 9½ x 12½, three hundred or more pages in each volume. The paper used will be the best quality imported hand-made paper, a paper that will be as lasting as can be made. As a supplement to the twenty volumes there will be twenty portfolios, each containing thirty-six of the large pictures 14 x 17, or in the complete set there will be seven hundred and twenty large pictures. These also are to be of the very best photogravure work. Every care will be taken to make the book the very finest sample of the bookmaker's art.

Mr. Frederick Webb Hodge, of the Smithsonian Institution, and editor of the "American Anthropologist," will be the editor of the work. President Theodore Roosevelt will write the Foreword Introduction. It will be published in parts, each part being complete in itself, as it will treat of certain tribes. It is proposed in the complete work to take up all the tribes, both in pictures and in text, of our North American Indians, who are yet in a primitive condition, picturing every phase of their life.

Mr. J. Pierpont Morgan's assistance in the work is in the form of an advance subscription to twenty-five sets of the work, this fund to be subject to my draft at the rate of \$15,000 a year. Most of these copies will be presented to foreign individuals and libraries. The use of this fund entails no restrictions or even suggestions in handling the work, I being simply supposed to do as I have in the past—work to the best advantage for the welfare of the work and publication.

EDWARD S. CURTIS.

## THE GENESIS OF A MODERN LENS.

[In the following first instalment of an article from our contemporary the "Central Zeitung für Optik" a clear idea is given of the steps through which a modern high-class lens passes from the glass-works to the camera. Expressed, as it is, in popular language, Herr Büniger's paper should prove deserving of study by those interested in their optical tools.—Eds. "B.J."]

DURING the last fifteen years there has been a wonderful advance in the construction of cameras generally, and hand cameras in particular, but the advances in lens construction have been greater still. The expenditure of intellect, trouble, and care involved in the production of the present-day anastigmat is known and appreciated by the initiated. To the layman there is apparently more value in the bright brass or nickel fittings, the bright red bellows and polished woodwork of a camera, than in the less pretentious looking lens, and the novice is astonished to hear that the latter in many cases costs far more than the rest of the outfit. Photographers, however, have become accustomed to the high prices of their lenses, and neglect the cheapest trash. Those who go in seriously for photography always choose good apparatus and lenses. Everyone knows from magnifying and opera glasses how cheap optical goods can be, and he who does not know the difference between ordinary and the higher optics may well wonder why five or six pieces of glass in a mounting cost so much. And yet the price is fully justified.

The facts as to the method of making a modern anastigmat are but little known to the public, and sometimes not even in commercial circles. Even now it is possible to hear a dealer say: "When an optician sits down and begins to grind, he cannot say beforehand that he will make an objective which will act in such and such a manner, or shall be specially fitted for a particular class of work. It is in most cases—chance." It would be a bad thing for optics if this were the case. If a dealer says this, what must the public think?

These articles are intended to sketch in simple language the genesis of the modern anastigmat, and in such a manner that even he who runs may read—and learn. As regards the theory and practice, only so much will be dealt with as is necessary to give a clear conception of the facts. It would entail, too, considerably more space than can be given to it.

### Making the Raw Glass.

The difficulties begin quite at the beginning, in the manufacture of the raw glass. The old opticians, with Fraunhofer at their head, made their own glass. As this was done only in a small way, and the science of glass manufacture was but in its infancy, the number of glasses differing in their constants was small, and, naturally, the glasses could not be compared with those prepared in the special glass works of to-day. The greatest success in recent years in this particular direction has been the pioneer work of Dr. Schott, who, in conjunction with and at the suggestion of the late Ernst Abbe, made the first special success in glass smelting. With a subsidy from the Prussian State, the well-known glass smelting works of Schott and Genossen were founded in Jena. To the new glasses of this establishment are we indebted for the possibility of making our modern anastigmats, and by altering the fluxes their optical constants were so altered as to fulfil the new requirements of the theoretical optician.

Optical glass, whatever its refraction and dispersion, must before all things be as free from faults as possible. That is to say, it must show no bubble, wavy streaks, lumps, or other imperfections. Further, the whole piece must be homogeneous in the strictest sense of the word.

### The Manufacture of the Glass.

The constituents of the glass are melted in clay vessels, the so-called "pots." According to its composition, the glass shows subsequently higher, medium, or low refractive index and dispersion. In the pots, which are slightly conical, the glass is heated far above its melting point and rendered quite fluid. Gases and other impurities are given off. The liquid mass is now well mixed, with constant stirring, in order to make it homogeneous. The throwing of a raw potato into the fluid mass helps the avoidance of bubbles.

When all is thoroughly mixed the cooling is begun. This must be effected with great precautions, and only very slowly. The homogeneity of the glass, after well mixing, depends entirely upon a slow and gradual cooling. If the glass cools down too quickly, it contracts unequally and stains are caused, which give rise to unequal refraction. In order to obtain this homogeneous cooling, the glass is cooled down very slowly a hundred degrees at a time. Such a cooling down as this often takes two or three months. Finally, when the whole mass has cooled down, the pot with its contents is broken. The irregular pieces thus obtained are cut into square plates. On two opposite sides of these plates two narrow windows are polished so that the whole of the interior of the plates can be examined. The sides are covered with an opaque crust, and this examination permits the rejection of the useless pieces.

The price of the glass differs according to its composition and the difficulty of manufacture. The newer crown and flint glasses, which are mostly used for anastigmats, vary between fifteen and thirty shillings per kilo (2½ lb.).

### The Optical Constants.

In order to determine the optical constants of the melt, pieces of a given angle are cut from small pieces. With these prisms a very exact spectrometric measurement is made with a spectrometer. These measurements are based on Fraunhofer's discovery of the dark lines in the solar spectrum. It is well known that white light is not homogeneous, but that it can be split up into rainbow-like spectral colours.

The five principal spectral colours are red, yellow, green, blue, and violet. Newton (1666), who first proved the composition of white light from the spectral rays, gave the number of the principal colours as seven, for he included orange and indigo in addition.

Fig. 1.

the above. Yet these play but a minor part, though all the colours gradually blend one into the other. The Fraunhofer lines, or strongest of them, are designated by the capital letters A to H. The lines A and B lie in the red, C in the orange-red, D in the brightest part of the spectrum, the yellow, E in the green, F in the bright blue, G in the dark blue, and H in the violet. By means of a spectrometer the refractive index of these lines is accurately determined in the glass to five places of decimals. The refractive index is referred to that of air, which is taken as unity. These measurements are performed in the glass works, but opticians usually determine them also for themselves.

Well determined types of glasses have been worked out, which are always made. Yet, in spite of the same ingredients being used, the constants of successive melts are always slightly different.

Before the manufacture can be begun, the calculations for the lens must be made. These calculations are the most difficult part of the process, and cause endless trouble and work.

### The Faults of Lenses.

In order to obtain a clear idea of the difficulties and the range of the calculations, we must first consider the faults of a single lens. In Fig. 1 we have a biconvex lens and a luminous point at an infinite distance, such as the sun, the rays from which we may call

der as parallel. The rays *a* and *c* are the limits of the beam, and the middle. At the same time *b* is the axis of the lens, about which it is centred. It is quite clear without further explanation that *b* passes through the lens absolutely without refraction. All other rays, as soon as they strike the surface of the lens, suffer refraction, and according to a given law. This deviation is caused by the difference in the molecular power of the two media—in this case air and glass.

The angle which the incident ray makes with the normal, shown by the dotted line, to the first surface is *x*, and the angle which the refracted ray makes with the same normal is *y*; then the sine of these two angles *x* and *y* is always in constant ratio =  $\frac{\sin. x}{\sin. y} = n$ .

This amount is always designated *n* when the first medium is air. The refraction, deviation, or bending of the ray from its original path then equal to the difference between the two angles, and *x* - *y*.

The refracted ray strikes the second surface of the lens, and suffers a second refraction according to the same law, and then continues its way till it cuts the central ray or axis of the lens. At this point is formed an image of the luminous point—in this case the sun.

This point lies, in this case, at the focus of the lens. The distance from the lens to this point is called the focus of the lens. Now, the nearer the ray is to the central ray or axis, the smaller is the incident angle—that is, the angle between the ray and the normal, or *x*. The result is that *y*, the angle of refraction, is also smaller. As the deviation is less, the ray, after passing through the lens, cuts the axis of the lens later than the marginal ray, Fig. 3. The foci of the marginal ray *B* and that of the ray *B* nearer the

Fig. 2.

s do not lie in the same plane, and the latter is further from the lens than the former. We thus see that the greater the incident angle the greater the refraction and deviation, or marginal rays have shorter foci than axial rays; yet the refraction always follows the same law  $\frac{\sin. x}{\sin. y} = n$  constant.

This defect is due to the fact that lenses are portions of spheres, and is called "spherical aberration." With a single lens this defect cannot be obviated, but only reduced to a minimum by the choice of suitable radii of curvature.

The rays which we have hitherto considered have been assumed to be parallel. Naturally, and especially in photographic work, non-parallel rays have to be considered, for all objects are at an infinite distance, and do not lie on the axis of the lens. We must differentiate, therefore, between rays from points within the axial plane, but which strike the lens at a more or less large angle with the axis, and those which, lying outside this angle, also strike the lens at a definite angle. These oblique and acute angle rays, within and without the axial plane, coming from a finite and indefinite distance, are actually the causes of astigmatism and coma—want of definition. Obviously, this fault cannot be obviated in a single lens, but only reduced to a minimum.

Up to the present all the rays we have been considering have been monochromatic, or of one colour. This convenient assumption, however, is not an actual fact.

Let us consider a single bi-convex lens, and let a ray of white light fall on it. This, as soon as it has passed the front surface, will split up into a number of coloured rays (Fig. 4). At the second surface of the lens this process will be continued, and consequently

increased, so that from a luminous point we have a coloured and indistinct image. In order to explain this, we must assume that light must be propagated, like sound, by wave motion. There is no other satisfactory explanation. As with sound, the shorter wave motions are shriller, so light, according to its colour, has shorter and longer waves. All known refracting media have the property, through their molecular power, of refracting the shorter wavelengths more than the longer. For instance, the red ray is deviated less from its path than the violet, and, as with a single lens—that is, a lens of only one kind of glass, and possessing only two radii—every colour has its own focus—that is to say, the images produced by the different coloured rays do not lie on the same plane. Thus appear the coloured halos in the image—the lens is chromatic.

For a long time this fault had to be put up with; it was obviated to a certain extent by using instruments of very small aperture, with the result that they were very poor in their power of admitting light. For this reason reflecting telescopes were used.

The first achromatic lens was made by the English mechanic and optician, Dollond, about the middle of the eighteenth century. Newton, a century before, had denied the possibility of making achromatic lenses. Through defective experiments he came to the conclusion that achromatism could only be obtained by absorbing the excess of refraction, and that only thus could the colour of any excess of refraction be obviated. The result was a system which was neither positive nor negative, but a plane.

About a century later the mathematician Euler again dealt with the achromatic lens. He made calculations and communicated with Dollond, who made some fruitless experiments. A few years later Klingenstierna, a Swede, experimentally proved the possibility of

Fig. 3.

achromatism. He used a combination of two prisms, and showed with these deviation of white rays without colour dispersion.

Dollond, as soon as he heard of this, again began his experiments, and soon gave to the world his achromatic lens. It was made only by trial and error, for at that time the method of numerically estimating the optical constants of a glass were not known. In spite of this, Dollond's lenses gained great approval and proved very good in practice.

As soon as Fraunhofer discovered the black absorption lines in the spectrum, in 1814, the optical constants of glasses could be enumerated, and the mathematicians could calculate out their formulae. In spite of this, for years many opticians worked purely by trial and error.

So far we have only learnt the defects of spherical and chromatic aberration, and only touched on astigmatism. To follow this subject up completely and learn the deformations that it causes would lead us too far astray in a superficial sketch such as this. There are other faults also, but these are the three principal ones.

The different coloured spectral rays are differentiated according to their intensity and activity into two main groups, the visual and photo-chemical or actinic. The visually luminous rays are those which lie in the yellow of the spectrum. If, therefore, an instrument is to be corrected for visual work, the calculations are principally confined to this part. As a matter of fact, a telescope is corrected for C and F, or C. D, and F, or D and F, and it is said to be visually corrected.

With a photographic lens, however, it is different. Here we have to deal with the photo-chemically active rays in the violet end of the spectrum about G. A lens may be only corrected for these rays,

but for general photographic work it would be useless, as one would have no control as to the sharpness of the image on the plate. Such correction is only used for astro-photographic objectives, with which the infinitely distant heavenly bodies are photographed, and the focus, having been once determined, is kept constant.

Optical correction enables us to see the image on the ground glass and the actinic correction ensures the sharpness of the image of the plate, which later takes its place. Thus photographic lenses are corrected usually for D and G.

LUDWIG BUNGER.

(To be continued.)

## THE DISTRIBUTION OF LIGHT IN GRATING SPECTRA.

(A Paper in the "Astrophysical Journal," Vol. XXI., 2.)

HAVING had occasion recently to plan for the construction of a short-focus spectrograph of fairly large dispersion in the visible region, the question of gratings versus prisms came up. Plenty of data regarding prisms are to be found in Kayser's new treatise in spectroscopy, but little or nothing seems to have been published regarding gratings, the only statements made being rough guesses. It seemed worth while to make a study of the distribution of the light (monochromatic) in the different spectra of a typical grating.

The apparatus which my assistant, Mr. Pfund, arranged for making the measurements was very simple, and the whole thing was accomplished in half an hour. The grating selected was a fairly typical one, the central image, rather dark and of a brownish colour, indicating that no very marked selective action for certain colours was present, and the first-order spectrum on one side extremely bright. The measuring apparatus, or photometer, consisted of a pair of Nicol prisms (one mounted in a graduated circle), a small piece of silvered glass, and a bright and uniform sodium flame. The silvered

obtained are recorded in the following table, eight spectral images being measured:—

Fourth Spectrum	Third Spectrum	Second Spectrum	First Spectrum	Central Image	First Spectrum	Second Spectrum	Third Spectrum	Fourth Spectrum
0.073	0.057	0.20	0.81	0.16	0.98	0.096	0.032	0.01

The numbers given are the squares of the sines of the angles, and represent the intensities of the image as fractional parts of the light transmitted through the first nicol. The intensity of the first spectrum on the right is as great as the sum of all the others together with the central image (0.94), which amounts to saying that half of the total light reflected is found in one spectrum.

It is frequently stated that a nicol reduces the intensity of unpolarised light by one-half. The reduction is obviously greater than this on account of the reflections at the two oblique surfaces, and to a slight extent by the balsam film. In the present case the surfaces of the prism were slightly dull, and I doubt if the intensity of the transmitted light was much over 40 per cent. of the original intensity. Calling the intensity of the soda flame 100, we get the intensities of the spectra by multiplying 40 by the fractions given in the table. The sum of these intensities (eight spectra and central image) is 75.6

Fig. 1.

glass can be made by dissolving the varnish from the back of a piece of modern mirror, and polishing with rouge. It is mounted vertically at an angle of 45 degrees with the axis of the nicols, and covers the lower half of the field (Fig. 1). The soda flame is immediately behind the polarising prism, and the grating stands to one side, as shown in the figure. By turning the grating the central or any one of the lateral (spectral) images of the flame can be viewed in the silvered mirror immediately in contact with the image of the flame seen through the nicols, and by turning one of them the intensities can be accurately adjusted. We first set the graduated nicol in the zero position, and then turn the other nicol to the position of extinction. The intensity of the restored light for a given angle measured from the position is proportional to the square of the sine of the angle. The central image can be located easily by watching for the reflection of the flame in the unruled portion of the surface. The results

Fig. 2.

which agrees fairly well with Rubens' determination of the reflecting power of spectrum metal for yellow (70 per cent.). This indicates that the ruling of the surface interferes in no way with the total reflection, which is what might be expected. The interesting point is that half of the total light is found in one spectrum. If specular reflection reflects 70 per cent., this means that we have 35 per cent. of the light in the first-order spectrum, or about one-third of the original amount.

To determine whether or not this was the case, I arranged a photographic lens, soda flame, and the grating in such a way that the lens pictured by the direct image of the flame and the first order spectral image side by side on a photographic plate (Fig. 2). A ray filter of aurantia was placed in front of the plate, to eliminate the action of the blue and green rays from the Bunsen flame, which would be present in the direct image, and absent in the spectral image. The spectral image was exposed thirty seconds, and the direct ten, and on developing it was found that the images had almost exactly the same intensity, showing that no error of any considerable amount had been made in the photometric work. Of course, the same intensity distribution might not, and probably would not, be found for other colours, but the results obtained with sodium light give a fair idea of what may be expected of an average grating.

The difficulty of ruling satisfactory gratings of very short focus (on meter or less), combined with the fact that only short lines can be

ed, makes it appear probable that for work of certain kinds better results can be expected with large plane gratings combined with chromatic lenses. Two flint prisms of 60 degrees would give us about the same average dispersion, and the intensity would be a little more than double that given by the grating, since two prisms in this description transmit 75 per cent. of the light, according to Koenig's table given in Kayser's "Handbook." The measurements which I have recorded were made merely for my own information, without any idea of publication. As they may prove of some interest to others, it has seemed worth while to put them on record. I have, of course, said nothing about resolving powers in considering the different types of dispersion pieces.

R. W. WOOD.

#### LECTURES AT THE R.P.S. EXHIBITION.

The following is the programme of lectures to be delivered at the Royal Photographic Society, during the forthcoming exhibition of the Royal Photographic Society:—

Thursday, September 19.—"With a Hand Camera to the Niagara Falls," H. O. Klein, F.R.P.S. Saturday, September 21.—"Eight Hundred Miles up the Nile," R. Falconer Jameson. Monday, September 23.—"South Africa in 1906," Harold W. Atkinson, M.A. Tuesday, September 24.—"In the Land of the Vendetta," Rev. T. T. Gage, F.R.G.S. Saturday, September 28, "Westminster Abbey," Joselyn Perkins, M.A., F.R.Hist.S. Monday, September 30. Some Celebrated Nesting Haunts of British Sea Birds," W. Wren. Thursday, October 3.—"A Year and a Half among the Alps," A. H. Dunning, F.R.G.S., F.R.P.S. Saturday, October 5. Wedgwood: His Life and Work," Harry Barnard. Monday, October 7.—"Ancient Egypt," C. J. Marshall, A.R.I.B.A. Thursday, October 10.—"The Romance of Insect Life," F. Martin-Duncan, F.R.P.S. Saturday, October 12.—"Some Dutch Places and People," C. J. Marshall, A.R.I.B.A., F.R.P.S. Monday, October 14.—"Lakes and Villages in North Italy," Rev. H. O. Fenton. Thursday, October 17.—"Adventures in Bird Land," Oliver G. Pike, F.R.P.S. Friday, October 19.—"My Experiences in the Jamaica Earthquake," Vaughan Cornish, D.Sc., F.G.S., F.C.S., F.R.G.S. Monday, October 21.—"Two Benedictine Minsters," E. W. Harvey Piper, M.S.A. Thursday, October 24.—"Bird Hunting in the Balkans," R. B. Lodge. Saturday, October 26.—"Beauties of the Alps," Louis J. Steele, M.I.E.E.

J. EDWARDS AND CO.—We learn from Messrs. B. J. Edwards and Castlebar Works, Ealing, W., that, from the 8th inst., Mr. B. J. Edwards is no longer connected with their firm, the technical management of which is now in the hands of Mr. E. J. Wall, F.R.P.S., well known to our readers as an expert in emulsion making, orthochromatic plates, and other branches of photography. Mr. B. J. Edwards also informs us that he is no longer connected with B. J. Edwards and Co. and that all personal communications should be addressed to "Wistow," Hayes, Middlesex.

EXHIBITION AWARDS.—This question received much attention from the Committee of the Bristol Photographic Club, who finally decided to give several plaques of equal value in each class, and to depart from the usual practice of placing the winning pictures in so-called order of merit. It was felt that any such attempt at "placing," even in the case of a big open competition, is bound to be unsatisfactory and against the best interests of pictorial photography. Whereas most art critics would agree closely in choosing the best eight pictures, yet probably no two would place them in the same order, owing to the idiosyncrasy of each critic.

OZOBROME, LIMITED, beg to announce that, in consequence of the increasing demand for Ozobrome materials, their factories at 96, Prince of Wales Road, and 1, Weedington Road, have been found to be inadequate, and they have therefore acquired more commodious premises at 122, Allcroft Road, Kentish Town. They will continue to supply materials for the Ozobrome, Ozotype, and gum-ozotype processes, and in a few weeks will be able to undertake, from customers' side prints, the making of Ozobrome prints and enlargements. They will also supply suitable papers for the oil process, and papers coated with plain gelatine for special photographic purposes.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between August 6 and August 10:—

DARK-ROOM LAMPS.—No. 17,825. Improvements in, and relating to, lanterns for photographic dark-rooms. Harry Duckworth Halstead, 51, Deansgate Arcade, Manchester.

APPARATUS.—No. 17,900. Improvements in portable photographic apparatus. Reginald Haddan, 31, Bedford Street, Strand, London.

CINEMATOGRAPHS.—No. 17,955. Improved device for looking at stereoscopic projected images, especially living pictures. Marius Nicolai Topp, 6, Lord Street, Liverpool.

MOUNTS.—No. 17,975. Improvements in photographic and other picture mounts. Benjamin Garfield Carpenter, 82, Victoria Street, Westminster.

EMULSIONS.—No. 17,976. Improved method of manufacturing emulsions and the like. Oscar Pirsch, 7, Southampton Buildings, London.

LENSES.—No. 18,121. Improvements in telephoto lenses. Alfred Edward Staley and Owen Wheeler, 19, Thavies Inn, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

ANASTIGMATIC LENSES.—No. 18,073. 1906. The invention is for a lens free from aberrations, the claim being for a lens consisting of front and back combinations, having in them the same number of lenses, each lens of each combination being made of the same type of glass as a lens of the other combination, and having substantially the same radii of curvature, but of opposite sign. The complete lens is generally composed of several glasses, two combinations at least being employed. The front combination, which is positive in character, is constructed in one of several well-known ways, so that central spherical aberration, coma, astigmatism, and chromatic aberrations are practically eliminated. No attempt is made to obtain flatness of field, though in some cases the conditions for obtaining this may happen to coincide partially with the conditions for freedom from the aberrations enumerated. When a suitable front combination has been obtained a back combination is formed as follows:—A number of lenses equal to the number of lenses in the front combination, and of substantially the same diameters are taken, the types of glass being chosen so that there are the same number of lenses of each type of glass as in the front. Each lens in the front may now be considered to correspond to the lens of the same type in the back. By "type of glass" it is meant that corresponding glasses should have substantially the same refractive index in the part of the spectrum for which correction of other aberrations is made, but the corresponding refractive indices to all parts of the spectrum need not be equal. The glasses may be chosen in order to free the back combination as far as possible from chromatic aberrations.

The character of the back lens, whether positive or negative, depends on the separations between the curves. When the order of the lenses has been so adjusted, keeping the aspect of the curves always as described above, as to make the separations between the surfaces as small as possible, the back combination will be negative in character. The complete lens will then form a telephotographic system, and the separations between the components may be varied in order to obtain different focal lengths.

In describing the lens the words "crown" and "flint" are used to denote simple lenses, in accordance with the usual workshop practice. "Crown" designates a lens having a positive

or convergent effect on a parallel pencil of rays, and "flint," one having a negative or divergent effect on such a pencil.

Separation between lenses always means the distance between the centre of the back surface of one and the centre of the front surface of the other. Separation between curves means the

distance between the centres of the curves, either in glass or air.

Particulars of a system, consisting of four lenses,  $L^1$ ,  $L^3$ ,  $L^5$ ,  $L^7$ , and illustrated in the accompanying drawing, are as follows:

Diameter of lenses .6 in.

$$\left. \begin{array}{l} r_0 + 2 \text{ in.} \\ d_1 .2 \text{ in.} \\ r_2 - 3 \text{ in.} \\ r_4 - 3 \text{ in.} \\ d_5 .05 \text{ in.} \\ r_6 + 1.7 \text{ in.} \end{array} \right\} \begin{array}{l} L^1 n_{D10} = 1.6112 \\ L^3 n_{D30} = 1.5137 \end{array}$$

$L^1$  and  $L^3$  are cemented in contact.

$$\left. \begin{array}{l} r_8 + 3 \text{ in.} \\ d_9 .2 \text{ in.} \\ r_{10} - 1.7 \text{ in.} \end{array} \right\} L^5 n_{D50} = 1.5137$$

$L^5$  is close to  $L^3$

$$\left. \begin{array}{l} r_{12} - 2 \text{ in.} \\ d_{13} .05 \text{ in.} \\ r_{14} + 3 \text{ in.} \end{array} \right\} L^7 n_{D70} = 1.6112$$

Separation variable.

Refractive indices of glasses:—

	$L^1$ and $L^3$	$L^5$ and $L^7$
Ray D .....	1.6112	1.5137
Ray G .....	1.6248	1.5273

An iris diaphragm may be conveniently placed about a quarter of an inch in front of the front surface.

With a separation of .2 between the back crown and flint, a focal length of about 13" is obtained, and there is good definition over a circle of about this diameter when the lens is used on moderately distant or distant objects. With shorter separations good definition is obtained over the same circle. With longer separations the central definition remains good, but the well-defined field is less extensive. Cyril Frederick Lan-Davis, 25, Newman Street, London, W.

**CINEMATOGRAPHY IN COLOURS.**—No. 26,671. 1906. According to the invention, negatives of records of two colour sensations alternating with each other are photographed by apparatus, which may be of the usual character for taking cinematograph pictures, but red and green transparent filters, or screens, are employed which are alternately brought into position as the photograph is being taken, so that a cinematograph negative is obtained in which there will usually be about double the ordinary number of pictures for a given subject, and in which negatives of records

taken with the intervention of the red filter, or screen, alter with those taken with the intervention of the green filter screen. The photographic material, or negative film on which the pictures are taken in the camera, will, of course, be coated with an emulsion which has been rendered sensitive to the action of red, yellow, green, and blue light. A positive is then taken from the negative so obtained, and is used in a cinematograph apparatus, which may be of the usual kind, except that it is provided with a device, or shutter, furnished with two colour transparent screens, with the usual opaque parts between them, so adjusted as to conceal the change from record to record, and to show the minimum of obliteration, the coloured transparent screen being of a character respectively similar, or sufficiently similar to those used in taking the records that the alternate red and green colour records are exhibited with the intervention of corresponding colour screens—that is to say, as each alternate colour record of the one character comes into position for exhibition, the correspondingly coloured screen will simultaneously come into position, and as each of the other alternate colour records of the other character comes into position for exhibition, the other correspondingly coloured screen will simultaneously come into position. A rotating shutter with two apertures, or transparent parts, and opaque parts between, of the same size possible to conceal the change from record to record, may be a convenient device for the purpose, if the apertures are covered by the respective coloured transparent screens.

In order to comply with the requirements of persistence of vision as regards colour, it will be necessary to drive the apparatus, both in taking and exhibiting, at a greater speed than is employed with ordinary cinematograph apparatus, say at a speed double the speed. It is found that a speed which will allow about thirty successive pictures to pass the aperture per second gives good results, causing the persistence of vision of the observer to give him the impression that the colours obtained from the alternating records are superimposed, or blended, so that the moving picture appears to him to be in its natural colours, or approximately so. George Albert Smith, F.R.S., Laboratory Lodge, Roman Crescent, Southwick, Brighton.

**MOUNTANTS.**—No. 9,105. 1907. The invention relates to mountants for photographs, which consists of a pasty substance, such as starch, paste, gum, or the like, applied to the back of a photograph, for the purpose of affixing it to a mount.

To overcome the objection of warping caused by many mountants a flexible paste mountant is made as below, which prevents warping when it is applied to a dry photograph, and is applied to a wet photograph allows both the photograph and the mount to which it is affixed to be straightened if they should be warped when they become dry.

The invention consists of a compound of the following ingredients, in suitable proportions, which need not be accurate proportions—namely, gelatine, glycerine, starch, or a starch paste, such as flour, cornflour, and the like, and water. Gelatine may be omitted, and isinglass or glue, or gum arabic instead. Suitable proportions are as follows: Gelatine, 1 part; glycerine, three parts; starch, four parts; water, the balance. By mixing the ingredients together a flexible compound is formed, which is to be applied in the usual way to a photograph, print, or the like, and affixed to the mount.

It has been proposed to mix 40 per cent. potato flour, 10 per cent. gelatine, 50 per cent. water, and 5 per cent. glycerine in conjunction with blotting-paper, for the purpose of forming a matrix for stereotype casting; but these proportions are unsuitable as a mountant for photographs. George Richard Holding, 62, Cavendish Road, Kentish Town, London, N.

**COPYING STAND.**—No. 28,000. 1906. The object of the invention is to manufacture a copying stand and its equipment in a simple and portable form, to fold up and occupy the minimum of space, and be convertible and adaptable to the several uses attaching to or necessary in, finishing the picture. Also when printing or copying photographs, to ascertain and register the distance between an object placed upon the support or at any point of the stand, and the lens of the camera fixed upon another part of the stand, and, further, to enable all focussing movements to be undertaken by the operator from behind the camera.

The invention consists of a suitable stand composed of a base frame or slide carrying the source of light. Upon this frame slide two telescopic frames; each sliding frame is movable towards or away from the centre of the base frame, and carries a folding support at one end, against or upon which may be secured the printing-frame, easel, or other apparatus.

Upon the opposite sides of these sliding frames to the notched scale, which is provided in previous apparatus, devised by the inventors ("B.J.," March 16, 1906), additional scales are marked in inches, commencing at the front of easel, secured to the folding supports, and continuing the length of the said frames. With the use of this scale one can calculate from the distance of the easel, from the centre of base frame, as indicated on the notched scale, the distance between an object placed upon the folding support or at any position upon the stand, and the centre of the fixed or base frame. This information cannot readily be ascertained by reference to the notched scales, as these only indicate the distance of the object from the source of light or the centre of the base frame.

Suitable notches are provided in one end of the inner sliding frame for receiving a suitable detachable spring handle. With the use of this handle all focussing movements may be executed by the operator from behind the camera or the like, to any distance up to six feet between the folding supports, providing each sliding frame is of a length to contain a scale in inches up to one yard.

This easel may, when required, be secured by similar means in a horizontal position on the stand, and serve as a table for supporting a light-screen and retouching desk, and, being adjustable in a transverse direction, a portion may be further utilised as a palette for holding brushes or other materials incidental to the work of retouching. The light-screen is preferably made independently of, or separate from, the retouching desk, and adaptable to any size or type of retouching desk.

Part of the improved equipment is a small studio for use in lighting and modelling flowers, fruit, or small still life studies, Arthur James Lambert, 250, Barkerend Road; and Charles Henry Land, 15, Alma Place, Thornbury, Bradford.

**WIDE PRINTERS.**—No. 25,613. 1906. This invention relates to photographic apparatus for printing, by artificial light or daylight, sensitised postcards, etc., and has reference to that type of apparatus which consists of a box-like arrangement in which is placed a light, the shutter and pressure pad of such apparatus being arranged so that each is closed entirely before the other begins to open, means further being provided whereby the pressure on the platen is increased after the shutter commences to open. The shutter is glazed with orange or ruby glass, or coloured with a non-actinic medium, and is so arranged that a weighted lever pulls it on to its bed and prevents white light escaping. In front of the shutter there is an inclined bed, or a carrier resting in the bed, to carry the negative or film, and over this a hinged lid, covered with a pad, shuts down on the sensitive paper. A spring arranged at the top of negative holds the paper in position; further, there is provided an adjustable guide, against which the paper is placed, so that the prints may be identical or so that the same may be at an angle, raised or lowered or more to one side as desired. A lever, either single or double, is arranged outside the body of the apparatus, so that on raising the lever the hinged lid comes to a vertical or other suitable position, in order that the paper may be placed on the negative or removed therefrom.

On depressing the lever or levers the padded lid is brought down, pressing the paper in intimate contact with the negative, the shutter being opened by the movement of the lever. A further pressure is then put upon the paper by the engagement of the lever or levers on projections on the sides of the lid. On raising lever the shutter is closed, and then the padded lid is raised to its original position. Daylight may be substituted for artificial light by placing the apparatus in front of a window, removing the back cover or slide thereof, and blocking out of light round the apparatus. Harry William Harold, of Stoke Newington, Norfolk.

**RAS.**—No. 20,781. 1906. The invention has for its object to

provide a camera having a back or closure adapted to carry a holder for containing sensitised material, capable of receiving photographic impressions, which is adjustably mounted on the casing to permit the holder to support the sensitised material in the focal plane at any desired position of angular adjustment. A further object is to provide a simple and compact arrangement of the parts connecting the back or closure to the casing whereby the usual appearance of the camera is not altered, and which will permit the back to be readily removed when desired. The first claim is for the combination in a photographic camera of a rectangular casing, having a circular aperture in its rear end of a removable back, therefore having a rectangular aperture and plates, having overlapping edges mounted respectively on the casing and camera back, one of the plates on the casing being movable, to enable the back to be detached. Kodak, Ltd., 57-61, Clerkenwell Road, London.

### Time Development.

Writing on the above subject in "Focus," Mr. H. T. Munkman gives the following table for rodinal developer 1:100:—

Temperature in Fahrenheit Degrees.	Development in minutes and seconds.			
	Portrait.	Architecture.		Landscape.
72	14	19:30	...	27:20
71	14:30	20	...	28
70	15	20:30	...	28:40
69	15:30	21	...	29:20
68	16	21:30	...	30
67	16:30	22	...	30:40
66	17	22:30	...	31:20
65	17:30	23	...	32
64	18	23:30	...	32:40
63	18:30	24	...	33:20
62	19	24:30	...	34
61	19:30	25	...	34:40

### Oil Prints from Bromides.

Writing in "The Photographic News" on the use of a thin gelatine coating to enable bromide prints to be used as originals in the Rawlins oil process, Mr. C. Welborne Piper gives the following working instructions: For gelatinizing the print, take one part by weight of gelatine (Nelson's No. 1 will serve perfectly), soak it in twenty parts of water, and dissolve in a water bath in the usual way, taking care that the temperature of the water in the bath does not rise above 130deg. F. When quite melted, filter through cotton-wool twice into a clean vessel that is kept warm by standing it in warm water, and then pour the gelatine into a clean dish large enough to take the bromide print. This dish should have been previously warmed by letting it stand full of warm water until wanted. Next take a fairly big pledget of clean cotton-wool, soak it in water, then squeeze out the water and ressoak in the gelatine solution. You are then ready for the print, which, if a large one, should have been soaked in cold water until limp. Drain off the cold water and immerse for a few seconds in a dish of water at about 90deg. to 100deg. F. Drain again and immerse quickly face up in the gelatine solution, pushing the print under the solution edgeways, so as to avoid air bubbles underneath. Remove bubbles on face by brushing over with the cotton-wool, then lift out print and hang it up to dry. It should not be in the gelatine for more than fifteen seconds, and should be hung up immediately on removal. Small prints can be gelatinized dry. Whether dry or wet does not affect process, but limp prints are somewhat easier to manage. The print should be

untrimmed, as finger and clip marks at the edges cannot be avoided, and you cannot prevent the gelatine from accumulating at the bottom edge. In two or three hours the gelatine will be dry, and the bottom edge, with its blobs of thickened gelatine, can be cut off. The print is then ready for the next process, bleaching, and fixing. Soak print in water until limp, and prepare a bleaching solution, consisting of one part of fresh stock ozobrome solution, added to two parts of water. For this stage you must work by weak artificial light (ordinary gas or candle light) until further notice.

Immerse print in bleaching solution, and keep dish rocking until action is complete—that is, until the image is brown and all trace of greyness or blackness has disappeared. Then wash very thoroughly in about eight changes of water. To do this, first remove the bulk of the yellow bichromate by a rapid series of rinses under the tap, then let the print soak in one dish while you rinse, wipe out, and fill a second dish. Lift out print, drain, and put to soak in second dish while you clean out and refill first one. Repeat this eight times, then proceed with next operation.

Prepare a fixing-bath containing 4oz. hypo, 1oz. soda sulphate, and 40 grains potassium ferricyanide to one pint of water. Put print in this and leave it for 40 minutes, taking care that it is properly immersed the whole time. The dish should be rocked for a minute or so now and again to ensure complete action of the bath. After this fixing process wash well for two hours in about a dozen changes of water, and then pigment.

After about half-an-hour's washing you can work safely by daylight.

#### The P.O.P. Problem.

There is another way, as the cookery books say (writes Mr. W. B. Ferguson in "Photography"), and I think a better one for securing both permanence and the tone wanted. This is first to fix the prints for fifteen minutes in the usual hypo-fixing solution, and afterwards to tone them in any combined bath one likes until the required colour is obtained, remembering, of course, that there will be a slight darkening of tone when the print is dried. I have used this method for the last six years, and found it very successful.

**CINEMATOGRAPE FILMS.**—Messrs. Gaumont have again shown their enterprise by issuing a film of the funeral scenes connected with the Belfast riots.

**"AMERICA ABROAD."**—The 1907 edition of this useful handbook is in no way behind the issues of previous years. It contains valuable, up-to-date information for the American tourist visiting London, Dublin, and Paris, together with an extremely useful section on "how to travel" and many useful hints connected therewith. It is published at the offices of "America Abroad," 8 and 9, Essex Street, Strand, London, W.C., price 6d.

**A VICAR'S PORTRAIT.**—"Recently," writes the Rev. H. B. Freeman, Vicar of Burton-on-Trent, to the "Daily Telegraph," "a young man called and asked the vicar of a village in my deanery for permission to ascend the church tower for the purpose of surveying the glorious view of the surrounding neighbourhood. Consent was willingly accorded. A few days afterwards the vicar received by post a snapshot of himself in the act of entering the only public-house in the vicinity. The victim told me that he remembered going into this hostelry on the morning in question to pay some wages."

**SOUTHWOLD OLD HARBOUR.**—A collection of photographs of Southwold Old Harbour is being published by Mr. F. Jenkins, of the photographic studios, High Street, Southwold. The illustrations, which number ten and are printed in platinum, are accompanied by historical notes by the Town Clerk of Southwold. The volume will be published at 12s. 6d., in an edition of 100 copies only. In drawing attention to this example of enterprise in a field closely allied to photography, we may mention that the collection of ten photographs and the history are published in an attractive and well-made box, which opens like a book. The contents are loose in the box, and can be readily lifted out with the aid of a ribbon provided for the purpose. The box is bound in a handsome blue cover, with gilt lettering, and is equally suitable to lay on the table or put on the bookshelf.

## New Materials.

"Verotype" Gaslight Paper. Sold by C. A. Rudowsky, 89, Chiswick Street, London, E.C.

The variety of printing materials at the disposal of the photographer is now so great—and the number of brands of one particular description of paper has equally increased tenfold of late—that it is increasingly difficult to discover notable features in any new introduction. Nevertheless, it is no exaggeration to say that in the particular gaslight paper to which we now propose to refer there is to be found a combination of qualities which lays upon the enterprising photographer an obligation to test them for himself in the anticipation that his work will be bettered, or that he will be able to secure equally good results in an easier way. "Verotype" paper, in chief respects, is worthy of a careful trial. It has a delicate beautiful surface approximately answering to the description of "semimatt," and it has a very great range of gradation. This conjunction of qualities in a print which without difficulty yields a black tone suggests that the claim of the makers, that it may be used as a substitute for collodio-chloride paper, is no idle boast. A trial of the paper will show that the prints come very near indeed to those on a collodion paper, whilst their permanency is unquestionably of a higher degree than that of a photograph printed and toned with platinum. The peculiar surface of the paper and degree of exactness with which it corresponds to a print of collodion character are matters which do not admit of realistic description. A print, but a few trials with a packet of paper will show that on point the maker has not raised the purchaser's hopes for nothing. As regards gradation, our trials were made with negatives quite opposite of what is suitable for the average gaslight paper. They were portrait negatives, containing the strong high-lights of a photograph in actual sunshine, a rather dark background and a light dress and hat representing a not inconsiderable amount of detail in almost the densest parts of the negatives. They were, as we have said, of more than the average density, being, in short, about the type of negative suitable for a collodio-chloride print paper. Using amidol as the developer, we obtained without difficulty or dodging a number of prints which did even justice to the negatives, and the difference between the results thus obtainable (from a negative of this kind) on the average gaslight paper was forcibly brought home to us by comparison with a set of the latter made only a few days previously from the same negatives, in which the detail in the dress was only faintly indicated when the shaded parts of the face were obtained of the correct tone. Our conclusion, therefore, is that, in providing "Verotype" for the production of C.C. effects, the makers have not only done so successfully, but have adjusted their paper to work at its best from a negative of the type required for collodion printing.

The paper we found much more rapid than is conveyed by the term "gaslight." From the negatives above mentioned—and they were of the greenish colour given by pyro-metol—we found 15 to 20 seconds, at 1 ft. from a 16-c.p. incandescent electric lamp, to be about right. The makers, it may be added, recommend a metol-hydroquinone developer of the following formula:—

Distilled water .....	24 ounces.
Sodium carbonate cryst. ....	3 ounces.
Sodium sulphite recryst. ....	1½ ounces.
Metol .....	24 grains.
Hydroquinone .....	72 grains.

And also a bath of 1:100 acetic acid as a sharp stop of the development. Our own preference is to omit the latter and use an ammonia fixer of the kind very usually used for gaslight work.

The prices of the paper are 7d. per dozen, quarter-plate size 1s. 1d., half-plate; and 2s. 1d., whole plate.

**"Rotona" Collodion Self-toning Paper.** Made by the Rotary Photographic Company, Ltd., Moorfields, London, E.C.

Varied as are the products of the Rotary Photographic Company, as witness their latest list which obtains a mention on another page, it is not until now that they have placed upon the market a print out paper of the self-toning class. In doing so now they have selected collodion as the vehicle of the self-toning emulsion, and the print thus possesses the special qualities which belong to a printing medium.

this description. "Rotona," as the new paper is called, if we judge from our trials of it, is quite fit to stand with the other stable products of the Rotary Company, and is evidently the result of careful manufacture applied to produce a material requiring the minimum of manipulation. The paper is printed to the depth usual with P.O.P., and placed, with or without a preliminary washing, in fixing solution (of 2 ozs. hypo per pint), which is rendered slightly alkaline with a little bicarbonate of soda. If the preliminary washing dispensed with the tone is less warm, but in any case the prints are toned under conditions which preclude the evil action of a fixing bath acidified by transference of acid from the paper. The fixing solution should be allowed to act for about ten minutes, and should not be—for this time of fixation—of less strength than the 10 per cent. recommended above. A weaker bath, used for a longer time, will yield warmer tones, and a stronger solution cooler tones; but our own preference is for the very agreeable brown tone given in a 10 per cent. bath without washing. These we like better than the blue and purple tones obtained with ease by the stronger hypo or the use of a 10 per cent. bath of salt before fixing. However, each will discover a procedure to his individual liking, and the bluish tints certainly supply prints of a colour very excellent for reproduction in half-tone. The "Rotona" prints are finished like any other halodion prints by blotting off the surplus moisture, and, short of actual ill usage, can come to no harm in the course of drying spontaneously or by heat. The paper is made matt, glossy, and creamed smooth, in each of which three varieties it is obtainable at a price equivalent to 22 quarter-plate pieces for 1s. A stouter paper also supplied, as "Rotona" card, the shilling packet of which contains 20 quarter-plate pieces. "Rotona" postcards in the three above qualities are also made up at 1s. per packet of twelve,  $5\frac{1}{2} \times 3\frac{1}{2}$  in.

#### CATALOGUES AND TRADE NOTICES.

THE ROTARY PHOTOGRAPHIC COMPANY, LTD., send us the latest issue of a list of all their products, showing the sizes, textures, and prices of their various printing papers and other specialities. The list will be sent post free on application.

MESSRS. A. E. STALEY AND CO., 19, Thavies Inn, Holborn Circus, London, C., send us a copy of a little magazine, "The Prism," issued by the Bausch and Lomb Company. Excellent in its printing and production, "The Prism" draws attention to the intelligent entertainment derivable from the photographic lens.

MESSRS. WRATTEN AND WAINWRIGHT, Croydon, have issued a list of their informative and slightly technical comments of the light-filters and safe-lights manufactured by them for orthochromatic photography and for the illumination of the dark-room. The list explains the differences in the optical quality of a filter desirable for different purposes, and includes a complete scale of prices for single and three-lens filters. The filters are, of course, suitable for use with plates rather than those of Wratten and Wainwright, and particulars of the exposure multiplying factor may be obtained.

SURREY SURVEY.—The Hon. Henry Cubitt, Lord-Lieutenant, has been unanimously appointed president of the Photographic Survey and Record of Surrey in place of the late Viscount Midleton.

VELOX COMPETITIONS.—Messrs. John J. Griffin and Sons, Limited, announce the following as prize-winners in the monthly "Velox" competition:—First prize (£2 2s.), C. Green, near Colne; second prize (£1 1s.), R. Barclay, Clonmel, Co. Tipperary; third prize (5s.), M. Taylor, Muirkirk; fourth prize (5s.), F. T. Norris, Essex; fifth prize (5s.), W. A. Attridge, Dublin; sixth prize (5s.), D. Deans, Larnock, N.B.; seventh prize (5s.), O. Goldsmith, Surrey; eighth prize (5s.), J. B. Irvin, Ayr; ninth prize (5s.), F. W. Walker, Leamington; tenth prize (5s.), F. H. Nield, Bristol; eleventh prize (5s.), A. G. Else, St. Helens; twelfth prize (5s.), W. F. Bache, West Bromwich; thirteenth prize (5s.), Wm. Findley, Aberdeen; fourteenth prize (5s.), Miss F. Wickham, Ealing. It should be mentioned in connection with these competitions that the competition is strictly for those who have never won a prize before. Hence, the prize-winners mentioned above are debarred from again competing, and the chance for beginners is thus increased. The competitions will continue each month until further notice.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 24.

Hackney Photographic Society. Outing to Banstead Common.  
Bristol Photographic Club. Outing to Bradford-on-Avon.  
Edmonton and District Photographic Society. Outing to Hoddesdon.  
Bowes Park and District Photographic Society. Outing to Burnham Beeches.  
Worthing Camera Club. Outing to Chiltonston Common and Thakeham Woods.  
North Middlesex Photographic Society. Outing. The Thames, London Bridge to Greenwich.

SUNDAY, AUGUST 25.

North London Photographic Society. Outing to Chorley Wood.

MONDAY, AUGUST 26.

Southampton Camera Club. Print Competitions.  
Bradford Photographic Society. "Suggestions on improving Prints, from a pictorial standpoint, and how to make the alterations suggested." J. H. Liebreich and W. H. Womersley.

TUESDAY, AUGUST 27.

Bristol Photographic Club. Business Meeting.  
Hackney Photographic Society. Points in Lantern Slide Making.

WEDNESDAY, AUGUST 28.

North Middlesex Photographic Society. "Enlarged Paper Negatives." H. Stuart.  
Leeds Camera Club. Lecture by Messrs. Hudson, Crossley and Lax.  
Edmonton and District Photographic Society. "Sports and Pastimes." Mr. Atkinson. Competition, July 27 Prints.

THURSDAY, AUGUST 29.

North London Photographic Society. Meeting at 8 p.m. Demonstration of Enlarging.

FRIDAY, AUGUST 30.

Photo Art Club. Annual Business Meeting.

## Commercial & Legal Intelligence.

A PICTURE POSTCARD DEAL.—At Brompton County Court last week, Messrs. G. W. Wilson and Co., photographic publishers, Aberdeen, sued Edward Grange, china merchant, Front Street, Brompton, under a judgment by consent for £114 for picture postcards. The judgment was obtained on June 4, but nothing had since been paid. Mr. Douglas Maclaren, who represented the defendant, informed Judge Stevenson that since the consent defendant had made a deed of assignment of all his goods to his creditors, to which the majority, both in value and number, had agreed. Mr. Robert Dalton, of Carlisle, had been appointed trustee under the deed, which had not been registered. Under the circumstances he left the matter in his Honour's hands. His Honour said he would have to make a reduced order for payment against the defendant. What was suggested? Mr. Milburn, the plaintiffs' solicitor, said plaintiffs did not wish to be hard. The original order was that the defendant should pay £2 a month. He believed that defendant was now receiving 25s. a week for carrying on the business. The assets showed something like being worth 25s. in the £, and he was inclined to think they were not being judiciously realised. His Honour made an order for 10s. a month against the defendant.

THEFT BY A CANVASSER.—At Falkirk Sheriff Court last week a well-dressed young man named Hugh Lees, described as a photographic canvasser, of Glasgow, admitted having in April received a gold locket, valued at £5, from Mrs. Elizabeth Ralston or Keir, wife of a labourer, residing in Laurieston, near Falkirk, for the purpose of having photographs therein enlarged, and thereafter returning the locket to her, and having appropriated it to his own use. The accused remarked that he had pawned the locket because he was short of money, but he redeemed it with the intention of sending it back, but he had again to pawn it. His intention was to lift it and return it. His Honour Sheriff-Substitute Watson imposed a fine of £2, with the option of twenty days' imprisonment.

ALLEGED CANVASSING FRAUDS.—The further hearing of the charge against a man named Stephen Mills at Chertsey, reported in last week's "B.J.," was continued on August 12. It will be remembered that the prisoner was before the magistrates last week, charged with obtaining 3s. from Mrs. Dedman, a widow, residing at Rowhill,

Addlestone, and that, after the evidence had been heard, he was remanded. Prisoner was represented by Mr. A. Emmanuel, solicitor, of Southampton.

A number of witnesses were called to prove the transactions entered into by the prisoner.

John Rowland, a groom, of "Woodside," Woodham Road, Addlestone, said he saw the prisoner taking the "maid's" photographs there. He asked him how much half-a-dozen photographs would be, and he said "One shilling and sixpence." Witness also had three large cabinets taken, to be also framed, for 5s. 3d. He went to see the prisoner about a fortnight after, and the latter said he would let him have them on the following week. Witness had received nothing but the proofs of the photographs.

Alfred George King, an insurance agent, of 3, Hare Hill, Addlestone, said defendant called at witness's house at 5 p.m. on June 14. He said the Dorchester Fine Art Photograph Company, of Dorchester, had decided to open a shop in the neighbourhood, and that he was getting photographs. He produced specimens of mouldings, and said his firm at Dorchester would undertake enlargements of photographs if the frames were paid for. Witness and his wife agreed to pay 5s. for a framed enlargement, and paid 1s. on account. A few days later Mills again visited the house and took three groups cabinet size, being paid on this occasion 4s. 6d.—2s. 6d. of which was towards the enlargement. The prisoner also took witness free, saying that he (King) could show it to some of the policy-holders he visited, and thereby get some orders for him. The only thing witness had received was a proof of the postcard. If he had not believed that prisoner's statement that he represented the Fine Art Company of Dorchester was correct, he would not have parted with his money. By Mr. Emmanuel: He had never heard of the Fine Art Company. It was the cheapness of the transaction which attracted him.

William Henry Welspring, a county court bailiff, of Dorchester, said that on April 17 he went to the prisoner's premises at 14, Victoria Road, Dorchester, for the purpose of distraining for rent. He saw no studio, and there was but little furniture on the premises. Outside the door there was a small blue paper and a frame with the words "Fine Art Photographic Company." At a later date he went again and made an entry of the things in the house. There were no cameras, printing-frames, or anything to do with the business of a photographer, in the house, nor was there a dark-room. When the goods were sold they fetched £2 14s. net. In reply to Mr. Emmanuel, the witness said he saw a camera in the house on the first occasion he went there. The prisoner showed him what he thought was an enlarging camera, and there were also large photographs of a greyish colour in the room. There was a chemist in Dorchester who undertook enlargements, and a man named Evans who made frames. The prisoner's family left the house on July 29, and he was told they had gone Southampton way. The prisoner showed witness some receipts which he had from Evans for money paid him.

P.S. Toop, of the Dorchester Constabulary, said he had known the prisoner since November, 1906, as residing at 14, Victoria Road, Dorchester. He saw him in April last at his house, where he went in consequence of complaints. Witness told the prisoner that he had come about a photograph, and that the police had had complaints of his taking orders which had never been executed. He also asked the prisoner if he had a studio, and he said "No." There were some photographs in the front room, and a card on the front door with the words "Fine Art Photo Company." Witness had been in Dorchester for five and a half years, and, as far as he was aware, there was no other person trading as the Fine Art Photo Company.

Mr. Emmanuel, addressing the magistrates, contended that there was nothing to show that prisoner was trading under an assumed name. He could put witnesses into the box to show exactly the reason for the delay. He suggested that what happened was that the people who gave the orders thought they were going to deal with the Fine Art Company—the persons who composed it they did not know—and also that they were going to get something for nothing. He further suggested that it was a mere breach of contract and not false pretences.

The magistrates retired, and on returning into court the Chairman said the prisoner would be committed for trial at the Quarter Sessions. They decided that the cases in which Mrs. Miles, Mrs. Underwood, Mrs. Smeeth, and Mr. Underwood were concerned should

be dropped, the prisoner being committed on the others, including Mrs. Dedman's.

The prisoner said Mr. Emmanuel had foreshadowed his defence in cross-examination. He was a photographer, and had taken thousands of photographs. The delay in the matter was due to the weather, and a death in his family; otherwise the Addlestone order would have been given in.

Bail was allowed, prisoner in £25 and one surety in a like amount.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed in our correspondents.

MARION AND CO., LIMITED.

To the Editors.

Gentlemen,—We beg to inform you that, after more than forty years of service as partner in the old firm, and managing director of the company, our Mr. Frank Bishop, whilst remaining a director, has retired from active participation in the business, and that our Mr. Gerald Bishop has been appointed managing director. Mr. Gerald F. Bishop continues as director, and Mr. J. G. Miller, Mr. J. Dickinson, and Mr. Thomas Clark, who are all old and valued servants of the company, have joined the board of directors.—Yours very truly,

For MARION AND CO., LTD.

22 and 23, Soho Square,

W. Piper, secretary.

London, W., August, 1907.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C. undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, and two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- W. Marshall, 31, Hart Street, Henley-on-Thames. Two Photographs of Park House, Henley-on-Thames.
- Isaac Perloff, 188, Commercial Road, London, E. Photograph of the Opening Ceremony of the Stepney Temple, on July 20, 1907.
- J. E. Reeves, 43, Hermit Road, Canning Town, London, E. Photograph of the West Ham United Football Western League Cup Team. Photograph of the West Ham United Football Team.
- F. G. Gegg, 13, High Street, Evesham. Photograph of the Evesham Junior Rowing Club.

RIGHTS IN A PHOTOGRAPH.—Would you tell me, through your Correspondence Column, if I should have to get permission from

to publish the interior of a church on a postcard?—F. P.  
There is no occasion for you to do so.

—Send us 2d. for postage and we will send you a copy which  
we have here, and which you need not trouble to return.

Penrose and Co., 109, Farringdon Road, E.C.

QUERY.—Will you kindly inform me, through the medium  
of your paper, what plans, light, and size I shall require for the  
erection of a studio for professional work, etc.?—J. THOMAS.  
Very good proportions for a studio for professional use are  
from 30ft. long, by 13ft. or 14ft. wide. As regards its form,  
whether the span roof or the lean-to are best. Opinions are very  
divided as to which is the better of the two. See article  
by Mr. Michell, on page 635.

WOODBURYTYPE PROCESS.—In the BRITISH JOURNAL OF PHOTO-  
GRAPHY, No. 2,181, Vol. XLIX., 1902, was a short article, dealing  
with the presses and their expense used in the Woodburytype  
process. Being a photo-process engraver in charge of that depart-  
ment, I endeavoured to try and find out the method employed to  
obtain a gelatine relief myself. I did not then realise the possi-  
bilities or vagaries of bichromate gelatine, and now a little know-  
ledge is worse than none at all, as I can make no headway; in  
fact it appears as if the difficulties are greater than they were  
at first, so if you could detail the process with the formula,  
which no doubt you are acquainted with, or advise me in any  
way whatever, I shall be deeply indebted.—D. RUTHERFORD.  
The Woodburytype process, beautiful though it is, is practi-  
cally an obsolete one, so far as its commercial working is con-  
cerned. It has been quite superseded by collotype and process  
plates. Its chief employment now is in the production of lantern  
slides. Seeing this, and knowing that the process would be of  
interest to the great bulk of our readers, we cannot afford  
space that would be necessary to give anything like useful  
details of the process. As, however, you appear to have  
access to libraries, we should refer you to page 388 of our volume  
for 1878, or page 602 of that for 1879. On both these full working  
instructions are given. They are also given in Burton's book on  
"Photographic and Photo-Mechanical Printing," published by  
Long and Co., Soho Square.

S.—There are several such methods. Yours may be different  
from others. We cannot say, but would draw your attention to the  
method in which the silver image obtained on first development  
was removed with ammonium persulphate, or that used in the  
Lumière process, in which the same thing is done with  
sodium hyposulphate.

U. LIGHT.—Can you oblige me with the address of the actual  
inventor of the mercury vapour light?—M. S.  
Messrs. Carl Zeiss and Genossen, Jena, Germany.

ENLARGING.—I was much indebted to you for your reply  
to my query regarding the use of a small Goerz-Anschutz camera,  
with 3½in. lens, for negative, designed for enlargement. I hope  
you will ask the following supplementary questions:—The lens  
discussed was a ———, listed to cover the plate in  
focus at  $f/4.5$ . You advised stopping down to  $f/8$ . (1) Does  
stopping down improve definition over the plate as a whole, or  
only necessary for the margins? (2) Is one well advised to  
use a lens with so wide an aperture if it cannot be safely  
stopped down to  $f/8$  as good as another ——— used  
at full aperture? (3) The ——— has a focal plane shutter.  
Is it reliable at the lower speeds? I do not know when I  
have occasion to wish anything shorter than 1/100 sec., and  
eventually I shall wish much less.—DUFFEE.

Definition all over the plate is improved only in the case  
of a very bad lens, certainly not in yours. We recommend  $f/8$   
not only for the sake of definition in the extreme corners.  
Certainly, it is as good, but the wide aperture is frequently  
an advantage when using the camera under bad conditions of  
light. For enlarging pure and simple, the smaller aperture is  
usually as convenient, but even here a large aperture means  
fewer exposures, and is often an advantage. (3) Our experience

is that it is. In general it is the highest speeds, if any, which  
fall short of the markings.

BUSINESS PHOTOGRAPHY.—Can you refer me to any publication, or  
article in a periodical, dealing with professional photographers'  
systems of accounts and bookkeeping, and with the usual methods  
of keeping a record of customers' orders, etc.?—G. C.

Articles on "Business Methods in the Studio" ("B.J.," March  
15, 22 and 29, 1907) deal with methods of bookkeeping.

W. H. DEE.—So far as we know, the firm is Maloni Patents, Limited,  
Ayr, N.B.

COLOUR FILTERS.—(1) Required, to coat a glass plate, 4½in. x 3½in.,  
with 10 minims of dyed gelatine solution. What is the best  
method of spreading the solution over the plate, so as to obtain  
a uniform distribution of the dye over the whole surface? (2)  
What is the best book to refer to for instruction in the prepara-  
tion of colour filters?—COLOUR FILTER.

(1) We know of no method of using such a small quantity of  
solution. You had better use a less strongly dyed solution, but  
more of it, and it is then easy to distribute the solution by flowing  
it on the levelled glass plate. You require about 20 minims  
per square inch. (2) "Practical Orthochromatic Photography,"  
by Arthur Payne, is as good as any.

PERPLEXED.—We do not think you can do anything of the kind. You  
accept the responsibility for an assistant's work when you engage  
him.

STUDIO QUERY.—I should greatly esteem your advice as regards  
improvement in lighting in my studio. I am forwarding a print  
of same. The studio, on first floor, is 31ft. long and 13½ft. wide,  
12ft. of glass on roof, and north side at east end of studio,  
leaving about 16ft. opaque at west end. Formerly I had an  
unobstructed side north light; now a large building runs parallel  
with the north light, about 1ft. from glass at bottom and 2ft.  
at top, finishing 2ft. higher than the side light. This makes  
the light nearly a top light, and is not at all satisfactory. I  
have been thinking I would have glass roof and side put in  
on south side at west end, building out side light in form of  
a large bay window. I should then be able to work at both ends  
of studio, and in the winter and afternoons make use of the south  
light. Do you think this would work satisfactorily? And if  
so, how much glass would it be advisable to have put in?—  
SOUTH LIGHT.

If you were to have the wall of the new building on the north  
side whitewashed it would help somewhat, as it would reflect  
some light from the south into the studio. We should certainly  
advise you to have the south light put in, as you would find it  
of great service. We see no need of the form of a bay window.  
If the glass on the south side is arranged as on the north it will  
be all that is necessary. Ten or eleven feet of glass, or the same  
as you have on the north side, will be quite satisfactory.

so, and the plans were passed by our local Board. Now my  
HALF-TONE ON LITHO.—I have occasion to print from some half-tone  
negatives upon lithographic stones, and am anxious to obtain an  
albumen formula for sensitising the stones. In my particular case  
the bitumen formula often used would be of no use. If you  
could kindly help me in this matter I shall esteem it a great  
favour.—GEORGE HERBERT.

White of four eggs (or albumen) .....	100 cc.
Fish glue .....	10 cc.
Water .....	1000 cc.
Ammonia .880 .....	5 cc.
Ammonium bichromate .....	5 grs.

The fish glue may be omitted, but it makes development easier,  
and the following formula, which contains no albumen, may be  
used:—

Fish glue .....	50 cc.
Water .....	1000 cc.
Ammonium bichromate .....	3 grs.

BUSINESS QUERY.—I have recently taken premises, and have com-  
menced building a studio in the garden in which to take my  
sitters. I had the permission of the landlord, in writing, to do  
so, and the plans were passed by our local Board. Now my

next-door neighbour threatens to stop the building, as it will be a nuisance to him, as he has bought his house, which is freehold. Can he legally prevent me from completing the building?—TROUBLED.

As you have the sanction of the landlord, and the plans have been approved by the local authorities, we do not see how he can. We should advise you to try and come to some terms with your neighbour, which you possibly may do if you tell him you will glaze the studio with ground or fluted glass, which cannot be seen through, so that his premises cannot be overlooked. That may possibly appease him.

**CARBON PRINTING.**—Having read many times that the carbon process is so easy to work, I have recently been trying my hand at it, using, for simplicity sake, the single transfer method. But I cannot get good, vigorous prints; they are all so flat. I cannot suppose that is due to the tissue, which I sensitise for three to four minutes in a solution of bichromate of potash—1oz. to the pint of water, with a few drops of ammonia added. If I were to use a stronger solution than that, should I get more brilliant prints?—NOVICE.

No, you would not. Your failure is probably due to the tissue being too highly sensitised for the negatives you are using. You must bear in mind that to get vigorous prints from feeble negatives a weak sensitising bath must be employed. Try diluting your present solution with an equal bulk of water, and immerse the tissue for only two or two and a half minutes. You must also keep in mind that for this process tolerably vigorous negatives are necessary, such as are required for platinotype.

**LENS QUERY.**—A relative (an amateur photographer) recently died and left all his apparatus to me. Amongst the lot is a cabinet lens 3½ in. diameter. It bears the name of "Lerebours et Secretan, Paris." It has no central stops, but there is one that slides in the hood of the lens. Can you tell me if it is likely to be a good lens and its probable value?—R. J.

The lens is not a cabinet lens, but the old whole-plate portrait combination, and probably has a much rounder field than modern cabinet lenses have. We can express no opinion on its quality, as that would necessitate a trial. We may tell you, however, that these makers had a fairly good repute for portrait lenses, though they were considered by some to be somewhat slow. The lens has very little market value, like most other very early lenses, at the present time.

**PURPLE TONES ON ALBUMEN PAPER.**—My employer wants me to get purple-tone prints. He has procured some albumen paper, which I have to sensitise on a sixty-grain-to-the-ounce silver bath for two to three minutes. I have tried the acetate and the borax baths as given in the "Almanac," but I cannot get the purple tones he says he must have, and if I cannot get them he tells me that he will have to get someone who can. Will you please tell me of a bath that will give good purple tones on albumen paper, as up till now I have had no experience with that paper?—LADY PRINTER.

With either of the baths you have been using you should be able to get purple tones if you print deeply and tone also deeply—that is, provided the negatives are suitable. From weak and feeble negatives it is impossible to obtain rich purple tones, whatever toning bath be used. Rich purple tones depend more upon the negative than the formula for the toning bath. As a rule, stronger negatives are required for albumen paper than for P.O.P.

**GEO. CUMMINGS.**—The fault in the bromide prints sent is due, not to the developer, as you surmise, but to the paper being fogged by light. The paper you are employing is far more sensitive than any of the papers of the Velox type, which you are used to. Therefore, as much care as regards light should be taken as with slow plates.

**FACTORIES ACT.**—In our business—a cheap one—we employ six girls, who commence work at eight in the morning and leave off at eight at night. They have half an hour off for dinner and half an hour for tea, and half of them work on alternate Sundays from ten till six, with half an hour off for dinner. The other day a factory inspector—a lady—called and told us that the

girls must have an hour off for dinner and half an hour and half a day's holiday a week, and that they must not work at all on Sundays. This, as you know, is only a very small town, and there are no real factories in it. Can you definitely if this lady inspector can compel us to do as she says because it will mean a great expense to us in carrying on trade—it will necessitate taking on more girls.—L. I. and

Yes; certainly your place comes within the Factory Act, whether the town is large or small, and you will have to comply with it, whatever extra it may cost you. The Act was passed to prevent the "sweating" of employees, especially of young persons, and that is what you seem to have been doing in the past. You must certainly not employ any of them on Sundays—that is against the law, which is a very serious one.

**W. W.**—The agreement you got the man to sign when you employed him is a very inequitable one. By its terms the man is prohibited for an indefinite time from carrying on business on his own account or entering the service of any other photographer in the county of York. In a court of law we surmise such an agreement would be held to be an undue restraint of trade, which is against public policy, and, therefore, null and void, in which case the man can set up where he likes and you cannot prevent him. Had the agreement been such that he should not carry on the business of photographer in the county for a year or two years from the time of his leaving you, it would have been more equitable and possibly valid.

**STEREOSCOPIC SPECIALTIES.**—We are informed that the collection of Mr. Theodore Brown in apparatus for stereoscopic photography is now carried on by Mr. B. K. Brown at 8, Villa Road, London, S.W.

**BRISTOL PHOTOGRAPHIC CLUB'S EXHIBITION.**—The date is October 12, entries closing September 23. The following are the classes and awards:—Pictorial, any subject. Open. Awards: Three bronze plaques, six certificates. Technical. Open. Awards: Three bronze plaques, three certificates. Lantern Slides, sets of five. Open. The awards will be given to single slides in the technical class. Awards: Three bronze plaques, three certificates. Pictorial subject. Open to residents in Bristol or within twenty-five miles radius. Awards: Two bronze plaques, three certificates. The secretary for the exhibition is Mr. J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

**"NATURE LECTURES."**—Now that the autumn session is close, and secretaries of societies are seeking to fill their programmes with interesting items for the instruction and entertainment of their members, Mr. Martin Duncan, F.R.P.S., the well-known lecturer, opportunely announces a new series of his fascinating lectures, which are illustrated by means of photographs, lantern slides, and animated pictures. There is no doubt that an evening of one of these lectures will draw a large audience, and is a popular feature in the programme of such societies as are large enough to secure a visit from Mr. Duncan, and secretaries should make early application for vacant dates, terms, etc., to Mr. Martin Duncan, 39, Bradley Gardens, West Ealing, London.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

giving an Exhibition. Mr. F. C. Tilney discusses a number of points which must be considered by any hanging committee conscientiously enters upon its duties. (P. 651.)

oil process. M. Puyo has published a brochure detailing his method of inking the oil print. Some full translated extracts on pp. 655 to 657, and a review of the book on page 664.

Unsuspected cause of failure in the use of a focussing magnifier mentioned on page 660.

Further points in reference to the colour of and material for curtains, and wall coverings in a studio appear on page 659.

J. McIntosh has recently described his method of ascertaining increased exposure required when using a yellow screen. (P. 661.)

Instance of the occurrence of blisters in bromide prints, for a very simple remedy proved effective, is the subject of notes on page 650.

her methods in catatype printing, a button magazine camera, pounds, and rotary surfacing of photographs are among the notes of the week. (P. 662.)

F. E. Ives writes to point out that a recent patent for a motion compensator in conjunction with a one-lens three-colour was anticipated by him in 1899. (P. 666.)

give a description of the simple Pfund photometer recently introduced by Mr. Wallace. (P. 660.)

hearing of the recent Chertsey canvassing fraud case at the Quarter Sessions resulted in six months' imprisonment for the canvasser. (P. 665.)

Nottingham canvasser charged with embezzling money from employers was fined twenty shillings or fourteen days. (P. 665.)

conviction for Sunday trading was obtained in the Cleithorpes Court last week against a photographer. (P. 665.)

## EX CATHEDRA.

### The Exhibition Season.

Before another issue of the "B. J." appears the last days for entries will be upon us. That for the Salon, Monday next, September 2, will be already past, and those with aspirations to honour at the exhibition "presented" by the Linked Ring must deliver their pictures unpacked at 5A, Pall Mall East, before six o'clock on that day. The last day for the Royal Photographic Society is Thursday, at 121, Regent Street, W., also unpacked, or Wednesday, September 4, if the exhibits are despatched by a carrier. Colour photography, it should be added, is to have an exhibition to itself under the auspices of the Society of Colour Photographers, the necessary accommodation having been provided by the editors of the BRITISH JOURNAL OF PHOTOGRAPHY. The entry form must reach the secretary of the Society, Mr. H. J. Comley, on September 10, whilst the exhibits themselves must be delivered to the "B. J." offices on or before September 10.

\* \* \*

### Developer Poisoning.

We have heard several times quite recently from correspondents troubled with skin affection from the use of metol developer, and while we are aware that there are persons of extraordinary susceptibility to all kinds of chemical solutions, we still have reason to maintain our opinion that there is really no cause, even with the metol developer, why inconvenience should be met with if more neatness in the manipulations be exercised. There is no need for the developer to come in contact with more than the tips of the fingers and thumbs, and in these circumstances no injury would be likely to occur to them. It is only when the developer gets between the fingers and on the backs of the hands, where the skin is thinner and more delicate, that trouble results. If any one who has suffered from metol poisoning were, for a time, to abandon its use and take to pyro he would see, after an hour or two's working, by the tell-tale stains on his fingers and hands, how much they have come in contact with the developer. With a non-staining developer this fact is not suspected. In developing plates, if one end of the plate be raised—a quill toothpick is a convenient thing to use—and the two corners taken between the finger and thumb of the left hand, the plate can be held up for examination; and, if the precaution is taken to hold the plate sloping downward so that the solution drains off away from the hand, only the inner portion of the finger and thumb will touch the developer. The same with prints; they can be dealt with in a similar manner, except that the fingers and thumbs of both hands must be used; but there is no need for more than their extreme tips to touch the solution even with large pictures. In the old wet-collodion days,

when acid-pyro and silver were used and stains were unavoidable, it was easy to distinguish at the end of the day's working who was the neat and who was the slovenly worker. Just the ends of the fingers and thumbs of the one would be discoloured, while the whole of the hands and perhaps wrists of the other would be badly stained. Metol has acquired a bad reputation, but that is due to its being used in a too perfunctory manner. If employed with neatness and a little more care, no ill-effects need be experienced from its employment.

\* \* \*

#### **Focussing Magnifiers.**

In the "Answers" column this week we briefly reply to a correspondent who complains that with a focussing-glass which he used successfully a few years ago he cannot now focus properly. He can even get on better without it. He does not state its form, and as there are several on the market at the present time, it is not easy to advise him. Some of the commercial patterns are not adjustable to suit different sights. Those that are not are usually constructed to suit normal visions, and they answer admirably so long as the sight of the user remains at the normal. But as one gets on in years the sight changes, the lenses of the eyes usually becoming longer in focus. Hence spectacles, which practically shorten it, become necessary. Only long-focus spectacles are required at first. But as time goes on and the eyes generally increase in focal length, lenses of shorter focus in the spectacles are required to compensate for it—"stronger glasses," as they are often termed. After this explanation it will readily be seen that a fixed focus magnifier, which may well suit a person while the eyes were of normal focus, would not do so when the sight had changed with age.

\* \* \*

#### **A Necessary Adjustment.**

This recalls to mind a circumstance that came under our notice a few years back. Calling on a friend, a professional photographer, fairly well advanced in years, he complained that his sight would not enable him to focus his sitters, for which operation he had to rely upon his assistant. In reply to our query as to why he did not use a focussing magnifier, he said that he used to, but he could not see at all with it now. It was brought to us—it was of the Ramsden eye-piece form, which is the best—and we saw at a glance that it was set for about normal vision. Finding that his spectacles were of eleven inches focus, the clamping screw of the instrument was loosened and the tube screwed out about half an inch, which was less than we thought necessary. Our friend was then asked to move it backward until a fresh pencil mark on the focussing screen of the camera was seen in focus. That required nearly another quarter of an inch. Finally, the proper focus was adjusted to suit his sight, and he was then enabled to focus his sitters as sharply as he ever did. Our friend had, as he told us, found it necessary to have the glasses of his spectacles changed from time to time, but it had never occurred to him that it was necessary to readjust his focussing magnifier in accordance with his advancing years. This is probably the case of the correspondent who wrote us on the subject, and probably of many others. A focussing magnifier is of little use unless it is set to the sight of its user, and unless that is done, in some instances, it is less than useless.

**Washing-Soda in Developers.** A case of some interest to photographers who use the pyro-soda developer came before the Mansion House Police Court on Thursday last week. A City firm were sum-

moned, under the provisions of the Merchandise Marks Act, for selling what were falsely described as "crystals," ten bags of soda mixed with Glauber's sulphate of soda. For the prosecution it was said soda crystals, or washing-soda, meant carbonate of soda worth £3 per ton, while Glauber salts were only £1 14s. a ton. In the end the defendants were fined a similar amount as costs. On a second sum they were fined a nominal sum. A good number of who employ the pyro-soda developer use washing-soda, indeed, some makers in their formula still mention form of soda carbonate, and practically it is as good the "crystallised carbonate" if it is of good quality. when washing-soda is used the supply is usually from the nearest oil-shop, or from the household soda which is supplied from the same source, and if this is largely mixed with Glauber salts—the sulphate of—it is quite unsuitable for photographic purposes. above is not the first prosecution under the Merchandise Marks Act for selling adulterated washing-soda, so we may well assume that the fraud is not uncommon. moral is to use the crystallised carbonate of soda as by photographic chemists. Its price is a little more the oilshop variety, but it can be relied upon as being correct substance.

#### **BLISTERS ON BROMIDES.**

THE discussion which took place on this subject in pages a short time ago suggested that the question was a matter of considerable moment to many workers. During the last week we have had some personal experience of one particular kind of blister, and as we found the probable cause and a certain preventive, our experience may be of service to others.

While conducting some experiments with sundry kinds of bromide paper and bromide postcards, we found some brands blistered most readily in circumstances that did not affect the other brands at all. This comes from those of our correspondents who suggested that only certain papers blistered. The blisters in a few cases were gelatine blisters, but the majority of them were water blisters. They were filled with water, and were produced almost instantaneously when the prints were direct from the hypo bath and put to wash under a spray. We were not aiming at the production of blisters in our experiments had a very different object in view—but blistering was such a nuisance that we had to devote some time especially to its investigation.

The size of the blisters varied from that of a pin's head to that of a two-shilling piece, and the big ones were fully a sixth of an inch. After watching their formation for some time, and after dissecting them, it became apparent that something of the nature of osmosis must be the cause. The blisters rose rapidly, but only when fresh water from the tap struck the print, and they were filled with water. It was evident that something of the water to penetrate very rapidly at the blistered surface, and it seemed probable that the something might be a small cavity filled with the hypo solution. It should be remarked that this was a strong solution for prints, contained four ounces of hypo to the pint. If we had such a cavity to exist and pure water to be brought into immediate contact with the film, it seems highly probable that the water will rush in and dilute the small quantity of hypo solution, and so raise a blister. It is significant that the blisters only occurred where the fresh water flowed directly on the print, that is, just where the film was most rapidly cleared from the hypo solution which it was impregnated, and it was obvious that a b-

can readily be formed if water can enter the cavity more rapidly than the hypo can diffuse out of it.

This hypothesis as to the cause of the blisters directed attention to two obvious methods of prevention. One was the device of immersing the print in a dilute hypo solution before placing it in pure water. The other was to wash in repeated changes of still water and to avoid running water. The prints were therefore transferred from the strong hypo bath to one of half the strength and left in it for five minutes. After this treatment they were still liable to blister under the tap, but to a much less serious extent. After six changes of still water they could, however, be put under a strong stream with impunity. This suggests that the theory is correct, though it does not prove it. In any case the treatment is absolutely effectual, and we have not seen a sign of a blister since we adopted it.

The facts that the blisters only occur with certain brands of paper and that they are nearly all paper blisters seem to suggest the use of defective paper. Very commonly the fault is ascribed to the gelatine, which is assumed to be imperfectly adherent to the paper; but

when the underside of the blister is coated with paper it is evident that there is not much wrong with the adhesion.

It may be remembered that a salt bath has occasionally been recommended after the hypo in order to prevent blisters. If the theory we have suggested is correct, it is obvious that many solutions should be preventives. It is not clear that salt can have any particular virtues, and it is probable that the salt bath acts in just the same way as the weak hypo solution. A preliminary alum bath is also a well-known preventive, and with this the non-appearance of blisters may be as much due to the filling of the assumed cavities with alum as to the hardening of the gelatine. It is not easy to get the alum out of a print; hence any alum in the cavities will almost certainly remain long enough to decompose any hypo that afterwards gets in. In this case blisters are not likely to be formed in the manner we have suggested. It may be added that the theory of the formation of the blisters is supported by the fact that a reverse action takes place if a blistered print is transferred from the water to a strong hypo bath. The blisters then subside, the water being drawn out of them by the hypo.

## OBSERVATIONS UPON THE HANGING OF PICTURES IN GALLERIES.

EXCEPT to those who have tried it, the "hanging" of a gallery of pictures may be taken to be an agreeable pastime, free from worry, and not involving too much mental effort. It may, indeed, be all this if the hanger is given to taking life easily, and declines to take the job seriously. Even then he must have sufficient softness of temper to take smilingly the jeers and the curses that will probably be heaped upon him by those who survey his work when it is done.

The hanging of a mass of pictures is, in reality, a task of never-ending responsibilities and heavy obligations; and to the man who is sensitive, nice, and naturally critical, it is one of exhausting effort both mental and physical. Coat must come off at the outset. Pipes either go out from inattention or are vigorously and extravagantly pulled at, according to habit and temperament. In less than an hour a visitor would see in the worker various unmistakable signs of conscientious application of labour, such as ruffled hair, derangement of neck-gear, and eke a broken brace.

### The Picture versus the Gallery.

Judging, selecting, and hanging, though each a separate operation, frequently react so much upon one another as to become practically one. What is a perfectly obvious course in one operation may become an impossibility in one of the others. In fact, the logical man, if he is nothing else beside, had better never embark upon the work: he will but be in an unprofitable state of eruption all the time. The reason for this is that picture-hanging involves an opposition of two necessary ideas and two different mental attitudes. For whilst there is an obligation to be fair to a good piece of work, there is also a responsibility for the general look of the gallery when all is done. Pictures are apt to run in clusters as to subject and style; but a collection should not show too marked a preponderance in any subject when it lays claims to a generality. This means that if 30 per cent. of the works selected are mud-flats with dark skies, and 1 per cent. are something else equally desirable, the whole percentage of the latter may find place, whilst half of the former may be "slung" instead of hung, and yet be no worse technically or artistically than the ones preferred. "Hence these tears" on the part of the senders.

But that's nothing! Everybody who makes pictures steels

his soul against such rough usage. Tears are really due when what is known as a "rotten thing" comes in imposing and admirable shape; fine and large of frame; expensively finished and beautiful to look upon from a distance. "That's obviously the centre for the long wall," says the hanger, who has it placed in a corresponding position on the floor; and if the logical hanger-on begins to object, he is cut short when he gets as far as, "But, my dear fellow—"

### The Decorative Trick.

"'Tis true, 'tis pity. Pity 'tis 'tis true." For myself, I think it an adventitious glory that a gallery should owe its first imposing impression to the frame or the size of works. At the same time, I am well aware of the value of such a moral effect upon critics, upon those journalistic bats and buzzards known collectively as the lay press, and upon the gilt "nobs" who pay shillings to walk in, through, and out in fifteen minutes. They, at any rate, will not pay again next year unless they are made to think the show "by way of being perfectly all right." Where there is no direct reliance upon the shillings of the general public, however, a hanging committee need surely never stoop to mere furnishing and decorating tricks. Therefore, I do solemnly trust that these mild observations will not add so much as one more altar-piece or overmantel arrangement for the autumn exhibition committees to deal with.

There is an aphorism which, though a trifle Ruskinian, is nevertheless perfectly practical. It is that the task which is beset with the hardest conditions brings the best triumph. Everyone may phrase it to their liking; but that's my own setting of my own experience. A sonnet has the reputation of being the most difficult form of poetic diction. Fourteen lines of ten syllables; octave, sestet, and a score of other conditions less often observed. But all the great poets have proved its form to be the perfect one for the expression of an idea, and their finest work is not infrequently found in that form. Architects and designers usually like to be well hedged with obstacles to keep them on the lines. Why may not picture-hangers first select their material solely by pictorial standards, and then boldly face themselves with the problem of hanging them with the best possible effect, omitting and adding nothing? Their task would certainly be more difficult than when they are allowed to make constant visits

to the rejected heaps in order to find something that will "pair" either in size, shape, weight, or colour. They will be less able to build up those wondrous groups of faultless symmetry which, after all, are only appreciated as one enters or turns at leaving the gallery; but they will be quite easily able to make smaller groupings, which will have the advantage of appealing to the eye at close quarters.

#### Wall Planning.

The main thing is not to have a ragged wall. My own feeling and practice has been always to maintain a steady weight from a line above eye-level and running throughout the mass, the tops of all the frames being kept accurately level, whatever size they may be. Those which are adjacent drop or rise at various distances, of course, from this line, and may be made to do so as symmetrically as possible; but the line itself should be traceable through all the groupings. It gives steadiness and homogeneity, and is much more in keeping with the architectural factors of a wall of a room than a free display that suggests target practice.

#### Classification.

To any who are new to the pleasures and pains of hanging, it may safely be recommended that a thorough sorting out of the selected works according to a *prima facie* aspect be first undertaken. Nothing is so restless and unsatisfactory as a mass of things having different "weight" and character. Let all passe-partout pictures hang together, and, further, all brown ones, grey ones, and white ones. Such an arrangement secures reposefulness. Next sort out all fussy things from quiet ones; any that are so peculiar as to defy classification being classed by themselves. The latter serve as "centres" for groups, and you may have several centres to one group if it is a large one. When such a system of classification is carried on throughout all the varieties of framing, due attention being given to size, colour, subject, and all other qualities that make pictures different from one another, it will be found that the work is practically done, all that remains to do being but mere pattern making, which may be carried out upon the floor until the arrangement is quite satisfactory.

In this process, a little re-mixing of the sorts, if very judiciously done, and not with too great contrast, allows the heavy groups to be lightened here and there, and the lighter ones to be strengthened, besides admitting of occasional relief of tint also. The system of classification brings order out of chaos; clarity from confusion.

As to the general pattern of groups, it will be found that a simple method is preferable. Horizontal lines are always safe, and if a set of works can be found similar in size and style, they may be regarded as a "god-send," and will look best by far if arranged in a solid order like the panes of a Georgian window.

#### Contrast Affected by Lighting.

There is a further matter upon which something might be said, since it does not appear to trouble the minds of the generality of picture hangers. This is the matter of lighting and the effect of pictures under varying lights. Most of the galleries built for the express purpose of exhibiting pictures are made with skylights, and these make a fairly equal illumination over all. But dull corners often occur, especially where screens are in use, and these corners may be made to serve valuable ends. It is by no means an invariable rule that a picture looks best in a strong light. The modern photograph of the so-called "artistic" variety is usually at its best with a dim illumination. On the other hand, the anathematised print with great contrast of tone and wealth of detail should be seen in brightest spots available. The reason for this is that a very strong light is so searching in the dark parts that contrast is minimised, and, *vice versa*, a dull light enhances contrast because it catches only the lighter parts. Watch a man in all but darkness. His face is scarcely recognisable; his clothes not at all; but his shirt-front and cuffs "come forward" out of all normal relationship of tone.

For this reason are the curb posts painted white around count lodge-gates, so that they may be seen on dark nights, when road and verdure defy close scrutiny.

If, then, a work is over strong in contrasts, its defect is mitigated by being placed where the light may not fall full upon it. If, on the other hand, it is flat and bald of detail, it will gain immeasurably in every way by receiving the subdued illumination that makes the utmost of its light parts whilst its darks are under-lit. In word, the dull light broadens and generalises: the bright light reveals everything. Skies, fields, faces, frocks, and all such passages that are of general high tone, but nevertheless are covered up with delicate shades and modelling when brightly lit, lose all these saving graces, and show a generalised passage of equal tone under low illumination. Similarly the grey-lights on dark clothes, trees, houses, and so forth either break up and relieve the dark passages or sink into them and are lost, according as there is light enough to see them or not.

#### The Bane of Glazing.

Now to another matter: we dare not, in a picture gallery, tilt a picture forward as is done in a room sometimes, because to do so would be derogatory to the dignity of the gallery, which would then smack too much of a bar-parlour. But there is no doubt that such a plan shows work to the best advantage because it gets rid of the reflection from the glasses, which is the bane of picture-seeing.

There appears to be no help for this annoyance. One may often see one's own face and nothing else when the picture is dark one. I cannot for the life of me understand, however, why, in the case of photographs, there should be any glass at all. They are not like paintings in the matter of taking damage from dust, or from uniqueness of production. What a lightened thing it would be to hang nothing but unglazed works, instead of the ponderous things that require carpentry to fix them to the walls. What a saving of risk from smashes! How easy the handling would become! And, above all, how much better they could be seen. I hear the murmured reproof that the glass gives them tone and quality; to which I reply that the tone and quality should be, and might be, in the print itself without any reliance upon a heavy green colour-screen to cut off 30 per cent. of the light. As to dust; a month or two in a large airy room will have no more damaging effect upon a perpendicular surface than may be instantly repaired by the flick of a silk handkerchief. I have had a fine photograph hanging upon a staircase for five years, and if it has altered at all in that time, the print is slightly more harmonious in tone than it was at first. Yet it has never had a glass before it in my time.

But the removal of glasses will not absolutely remove the reflection nuisance. All plain surfaces have this bad habit if they happen to be at the proper angle of incidence. Silver-prints, carbon-prints, and gum-prints have all more or less an altered appearance from certain points of view. Even the positively "matt" surface gets a greyness in its dark parts if seen at a certain angle.

#### The Golden Rule.

The golden rule is to have the eyesight going in the same direction as the light. When those conditions prevail the work is seen properly; but never otherwise. When pictures are hung too high, the gaze, being directed upward, finds upon them the reflection of the skylights above. With glazing this is easily obvious; but in every case the phenomenon exists, although its effects may be reduced to a minimum with certain surfaces. In the direction of vision and that of the illumination coincide exactly, and at right angles to the picture surface, then, of course, a perfect reflection occurs; but this is seldom, if ever the case in a gallery, though common enough in dwelling-rooms.

The ideal gallery for seeing pictures, not for any other, I admit, would be one where a platform raised the spectator a foot

so, so that he always gave a slightly downward glance. This would come to the same thing as tilting the pictures forward; but would have the advantages of perpendicular hanging, no loss of light on the works, and no upward staring with its accompaniments, a headache and stiff neck. As it is, the works immediately below the eye are always most comfortably seen and look their best.

### The Velarium.

Some galleries can afford the luxury of a velarium, and where this is possible a good deal of reflection trouble is eliminated by cutting off of the bare image of the source of light. The illumination is diffused, and attacks the picture more equally from every point. Cast shadows are mitigated—a consideration in oil paintings. In some cases the velarium stops short a few feet of the side walls and admits a margin of strong vertical light, whilst the spectator remains in a grateful shade. It is nice to have one's eyes comfortably shaded, and it prevents gallery fatigue very greatly; but the pictures, under this

arrangement, wear a forced look and suffer in various ways. This plan, which was tried at one of the "International" picture shows some years ago, has not been adopted since, except in a modified form.

At the New English Art Club galleries, in Dering Yard, Bond Street, a narrow velarium of diaphanous material sufficiently mellows and diffuses the daylight, whilst at night its action is quite perfect; for immediately above and behind it run two lines of small inverted incandescent burners, close set, which flood the room with a mellow but penetrating veiled white light, whereby works in colour are almost as well seen as by daylight. This little gallery is certainly one of the best lighted in London. Most others are hopelessly inadequate in their artificial lighting arrangements. The larger galleries seem to rest secure in elaborate electric fittings and switches; but there is no better light than the incandescent gas mantle affords for seeing work in colour or in monochrome.

F. C. TILNEY.

## M. PUYO'S TECHNIQUE OF THE OIL PROCESS.

[The enthusiasm with which M. Puyo, M. Demachy, and other members of the Photo-Club de Paris have taken up the Rawlins oil process was evidenced in last year's exhibition of the Photographie Salon, and it is therefore no surprise to find that as a result of the further experience of these indefatigable French workers a handbook of the process has been added to the list of photographic text-books which appear with the recommendation of the Photo-Club de Paris. In this M. Puyo gives a most lucid exposition of the principles and practice of the process as adopted by himself, and the following should be certain of a careful study from those working the *Procédé Rawlins*," appears on another page under "New Books."—Eds., "B.J."]

M. Puyo attaches the utmost importance to the oil process as a means of pictorial expression on account of its unique facility in permitting any control of the scale of tones as a whole, and also locally—in the latter case, however small a portion of the print may be selected for such local treatment.

1. Under-exposure increases the contrasts, over-exposure decreases them.

2. A hard ink increases the contrasts, whilst a softer ink modifies them.

3. A different ink may be used in different parts of the print, contrasts being raised in some portions by means of hard ink and lowered in others by means of a soft.

In the treatment of values in a print locally:—

4. The tones may be modified by adjusting the deposition of the ink. By the use of a fully charged brush a full deposit will be given to the print. By applying a hard ink very lightly a grey tone is the result, whilst any portion may be allowed to remain white by refraining from inking it. In other words, much may be done by under-inking.

In the other direction, by using a softer ink, the surface can be persuaded to take up more and more ink, and tones as deep as black as can be wished may be thus produced by over-inking. In short, the conjunction of the two systems under and over-inking permit of practically every effect from white, through a scale of greys, to intense black.

5. The time of drying also affects the final result. During a comparatively long time which is occupied in drying, advantage can be taken to further modify the print by gentle action, using a fine linen rubber or eraser, one or other of which may be used to lighten any given tone up to pure white.

With these comments on the essentials of the oil process, M. Puyo proceeds to discuss the materials for working.

### Papers, Inks, and Brushes for the Oil Process.

The beginner is recommended to use, in his first attempts, the special paper placed on the market under Mr. Rawlins'

directions. He will find as he gains skill that he can use almost any make of double transfer paper. In selecting any particular brand he should look for two qualifications:—

1. The surface should have as perfect a matt as possible, in order to obtain the necessary brilliance of the high-lights.

2. The gelatine film should be of a kind which does not prevent the drying of the ink. Papers present certain inexplicable differences in this respect.

As regards inks, a litho. ink is the most frequently used for the hardest ink, a copper-plate ink for one somewhat softer, and the "ivory black" oil colour of the artist for a still softer material. By using a mixture of litho. and copper-plate inks one of medium hardness is obtained, and another degree of additional softness may be secured by an admixture of some medium with the ink, such as varnish, Haerlem fixative, or mineral spirit.\* The beginner is advised to commence with black inks, but he may obtain any colour to his liking by mixing one or other of the above with coloured litho. inks.

Two kinds of brush are advised by M. Puyo, the first a so-called fitchet hind's-foot and the second the straight fitchet. The former is chiefly used for practically all the work, as its form eminently fits it for the various touches which are necessary in inking the print, and which are very clumsily done with the straight brush. The latter serves only for joining up, removing the excess of ink, and for softening portions of the print; in short, for the accessory portions of manipulation. It is well to have a number of the hind's foot brushes, so as to be able to take up a new one without cleaning that already in use, two or three of each size—costing from four to six francs each—and one or two of medium size should be sufficient. Those of the straight kind should be of different sizes.

### Sensitising and Printing the Paper.

M. Puyo insists on a comparatively weak solution of bichromate containing not more than 2 or 3 per cent. He sensitises by one of two methods:—

(a) *Immersion*.—The dish is filled with 2 per cent. bichromate

\* See footnote, p. 656.

of potassium or ammonium, the sheet of paper immersed and allowed to soften, gelatine side upwards. At the end of a couple of minutes the paper has absorbed all it will of the solution, and will not gain anything by remaining longer as regards sensitiveness. In sensitising several sheets at a time, as is usually required to be done, a second piece is inserted film side upwards as soon as the first has flattened, and the third is likewise introduced after the same time, an occasional movement being given to the solution. When the last sheet has been immersed the first is removed from the bottom, and, if seen to be uniformly saturated with the bath, is hung up to dry. The second and other sheets are removed in like manner, the whole operation requiring only about five minutes for six or eight sheets. By this process the sensitising must take place the day before printing, as the sheets require several hours to dry.

(b) *Sensitising by Brush.*—A much more rapid method of applying the sensitiser consists in using a 6 per cent. solution of ammonium bichromate to which is added at the time of use twice its volume of alcohol, 90 deg. Potassium bichromate must not be used, as it is precipitated by the alcohol. The sheet to be sensitised is placed on blotting-paper or card, pinned down, and the sensitiser rapidly applied with a flat hog's-hair brush, first in one direction and then in another, leaving no portion uncovered. Markings will still be visible, but may be removed by going over the print quickly with a goat's-hair brush, which takes up the remainder of the alcohol and equalises the coating. When the sheet is hung up to dry there must be no superfluous liquid upon it, or markings will occur when it comes to be inked. Ten minutes to a quarter of an hour is sufficient for the print to dry. The sensitising bath does not keep, and should be thrown away.

M. Puyo uses an Artigue photometer, giving thin negatives  $\frac{1}{2}$  to  $\frac{2}{3}$  deg., fairly vigorous negatives 1 deg., and those of greater density  $1\frac{1}{2}$  to 2 deg. But the time of exposure which should be given depends not only on the general density of the negative, but on the particular state in which it is desired to bring it in order that certain portions may be in a proper state for inking. For example, in the case of an under-exposed negative with a good deal of clear glass, little detail, and dense high-lights, a sufficient exposure is given for the shadows of the print to take up a hard ink in the ordinary way, the lighter portions of the subject being "developed" with a softer ink. The principle, in short, is to expose a negative in such a way that all portions of the subject are suitably exposed for one or other of the inks at the worker's disposal, from the hardest to the softest. If the negative as a whole is grey and lacking in contrast, it is well to distinctly under-expose for a hard ink, as under-exposure tends to contrast. In the case of a hard negative over-exposure will be employed, but without overstepping the time suitable for a hard ink. The above may be taken as a general rule, for it is not practicable to go to great extremes in using an extra soft ink. The only cause of total failure is to give an extraordinary over-exposure.

After exposure, the prints are washed in frequent changes to remove the bulk of the bichromate, after which they are left to themselves. Half an hour is a sufficient time for washing, but several hours will do no harm. It will be found that when the bichromate is completely washed out the image has almost disappeared. The prints need not be inked immediately, but may be allowed to dry and kept for at least several months. To prepare them, however, for use, the gelatine surface of the sheet, on withdrawal of the latter from the washing water, must be mopped so as to remove actual drops of water and to deprive the print of the larger portion of the water absorbed in it. This is done with blotting-paper, or if the best quality is not obtainable, between cotton plush, the gelatine surface of the print being gone over with a ball of

butter muslin. After this treatment the print is laid on inclined board (which is covered with damp blotting-paper) and is ready for inking.

Dust being a frequent cause of failure owing to the particles settling on the print and causing the adherence of the ink, it is well to sponge down the working bench with a duster free from fluff, and to wear protective silk sleeves which will prevent lint being removed from the clothes.

### The Principles of Inking.

A large clean glass being placed on the table, M. Puyo takes a little hard ink on the end of a palette knife and spreads it on the glass. The inking-knife of the lithographer, being a little stronger, is often convenient. If the ink is to be tinted a little bistre or blue is mixed with it, and the whole spread into a thin film. This done, the large hind's-foot brush is laid on the ink, allowed to rest a minute, and raised again. The brush has taken the ink, but before applying it to the print it is well to equalise the ink which it has taken by tapping the brush lightly on one part of the glass; it is then ready for applying to the print. Though the method of inking is easily taught by demonstration, the beginner will have to study for himself the different methods from descriptions which are not easily expressed in print.

(a) The first maxim of inking is to make each application as gently as possible: all force is fatal to success in the process. Gently applied, the ink is easily deposited on the print, but it will not adhere if violence is used. The major cause of failures in the process are due to disregard of this precaution. The hind's-foot brush is held lightly, and not tightly, between the thumb and second finger, the first finger guiding the second, the third finger separate, and the little finger in the palm, somewhat after the manner of a painter who affects "style" and the wrist is kept flexible. The fingers holding the brush should not grasp it by the hairs, but above the enlargement of the handle.

(b) If the print is over-exposed the ink will appear unmanageable, but if the paper has had the right exposure the ink will take nicely to the print. Those accustomed to the process will feel from the first application whether the ink is of the right composition for the print.

(c) Inking should always be commenced with a hard ink which may be softened as the hand feels it to be necessary, and inking should always be done by a series of operations that is to say, by applying a series of deposits to the final image. If too much ink is put on at once it has to be taken off, and in doing so the gelatine surface may be easily damaged.

### "Touches" in Inking the Oil Print.

In applying the ink a certain elastic touch is employed simultaneously with (1) a sweeping and (2) a twisting movement. The subject being brought out by these movements finished by a tapping action. The hind's-foot brush is charged with ink and held with its "heel" towards the worker, a given portion of the print. On pressing it slightly the hair bends and spread, and thus, in consequence of their oblique mounting in the brush, recoil slightly. The grasp of the brush by the fingers is relaxed so that the brush rises by the elasticity of its hairs; it is again pressed, and the operation repeated again and again. In this series of movements the tip of the brush does not leave the paper, and if the effect is now examined it will be seen that the ink has been deposited all over the portion, but not equally, the grain being coarse and irregular, and the result only a rough suggestion of the subject. The further deposition of the ink is done by a certain triple movement consisting of pressure, sweeping, and twisting, all of which are done with the ends of the fingers and the palm of a rapid deposition of the ink, the handle of the brush being held between the thumb and second finger. It is, in fact,

sort of "tickling" of the gelatine surface, and when skill has been obtained in it the brush seems to humour the paper, the thumb and fingers not tiring after hours of work. Finally, the inking is done by tapping either with the same brush or with one of the straight variety. In this latter part of the process, again, no force must be used. The brush is held perpendicularly above the plate and very light taps given, raising the tip of the brush a hair's breadth above the print. The whites are cleaned by this process, the grain becomes fine, the half-tones appear, the shadows are strengthened, and the print is completed. If the tapping, however light, instead of producing this result, appears to remove the ink, and if the grain does not become fine, the ink is too hard for the exposure which has been given, and must be softened. On the other hand, if the whites do not clear up, the print appearing to absorb the ink all over, and if certain portions are sunk in dark fog, the print is over-exposed, and requires a harder ink. If none is available, there is the remedy of "sweeping," of which M. Puyo writes below.

#### Accessory Touches in Inking the Oil Print.

"Sweeping," as M. Puyo defines it, consists in treating the print with a brush in the method employed in sweeping a carpet. The superficial action of "sweeping" cleans the whites (raised parts of the gelatine) and leaves the blacks (depressions in the gelatine). Sweeping thus increases the contrasts, and if the print shows signs of veiling, gives it a certain brilliancy.

A series of sharp dabs by means of the brush held perpendicularly to the print removes the ink all over, in the shadows as well, as in the high-lights, and serves to clear up any part which has been over-inked. It should be regarded as a quite exceptional means, for the safe method in applying the ink is to do so by successive small applications. In principle this last method is similar to tapping, the difference between them being only one of degree.

#### Adjusting the Ink to the Print.

The beginner in oil printing is recommended by M. Puyo to consider the prime object of securing intense blacks and pure whites in the print. These two extremes, in the majority of cases, are placed next to one another in the print. In a landscape the trunk of a tree placed in shadow stands black against the clear sky, whilst in a portrait the eye usually comes on the light side of the face. The tree trunk must be persuaded to take the ink well while the sky remains clear, just as the eye should print strongly without the well-lighted portions of the forehead and cheek-bone being veiled. There are thus three cases:—

1. By light tapping the ink can be picked up from all over the print. The shadows at each application of the ink gain intensity, but lose this intensity very quickly. At the same time the whites are veiled and become about equal to a half-tone. The plan of imparting sharp blows to the print instead of removing the ink seems to intensify its adherence, and the behaviour of the print in this way is a sure sign that it has been over-exposed for ink of this particular hardness. It is impracticable to make ordinary litho. ink any harder, such a print is of no use except for transformation into a light effect.

2. By tapping the print the portion operated on takes up the ink gradually and shows normal contrast. In this case the print has been correctly exposed for litho. ink, the use of which can be continued. These conditions, in M. Puyo's opinion, are the most favourable to latitude in modifying the oil print. It is possible to make the grain finer or coarser, and to adjust more or less the contrast in the different portions of the print, both being the result of the facility of treatment possessed by a print which has had ample, but not too great,

exposure. The question of grain is simple, since the hard litho. ink is not crushed fine at the first application of the brush. It assumes at first a regular grain, which gradually becomes finer as the tapping action is continued, and the worker, even when using a smooth paper, can give strength and breadth to the subject, say in the case of a fairly large head, or vigour to the foreground of a landscape. He can also adjust the grain in the different planes of a landscape in order to assist the aerial perspective or to suit the nature of the subject. This he cannot do if an insufficient exposure compels him to use a soft ink at the start, inasmuch as such an ink immediately gives a fine grain, but without the least vigour. It is therefore better, in M. Puyo's experience, to give the print a right exposure for a hard ink, which is quite easily done when using a photometer.

3. If when continuing the tapping movement the ink takes with difficulty, the shadows not gaining in intensity, it will be found that even if the action is done more vigorously the black deposit will lighten, the half-tones will become granular and without good modelling. A more pronounced tapping movement will produce an immediate lowering of tone, all of which shows that the print has been under-exposed for a hard ink and requires the latter softening by the incorporation of some copper-plate ink. This admixture can be made in small doses, in order not to exceed the precise degree of softening which is necessary, and it is better to work at first with an ink which is a little less soft than may be used, since one too soft gives the effect of over-exposure. Since the action of the softening constituents of the ink is very marked, a morsel of copper-plate ink, or of varnish, such as one will take up on the end of a match, is sufficient to work a transformation in the action of the litho. ink.

#### Precautions in Inking.

M. Puyo insists, again, on the necessity of taking the inking by easy stages, giving one application and intensifying this by successive use of the hind's-foot brush, avoiding any such action as may compel the worker to remove ink. Also, after each application the tapping action may be carried out almost completely before giving a further application of ink. In this way the print better retains its ability to respond to treatment. In all these movements all stiffness of the wrist or fingers should be avoided, and the movements of pressure, sweeping, and tapping made light and gentle.

In taking up a subject, the best course is to commence the inking in the portion containing the object of interest, and to keep this always in a further stage of development than the surroundings. There is no difficulty in adopting this course, which is the best one whether the subject be a portrait or a landscape. Thus in a landscape, when the object of interest, which is usually in the middle distance, has been inked, the foreground and the distance are next completed, and the result of such a procedure is to obtain a print which is much more harmonious throughout. Should the result of the whole process not satisfy the worker, the inking can be entirely removed with a sponge dipped in essential oil, which removes the image, the print being then allowed to remain for a few minutes in water in order to allow the gelatine to swell, and, after blotting off superfluous moisture, again submitted to the inking process. The gelatine possesses surprising resistance, though it may sometimes happen that when inking has been completed particles contained in the brush or in the ink attach themselves to the print, usually in the high-lights, where the gelatine is soft. The best means of removing them is to wipe the print with a wet sponge. Similarly, fragments of hair from the brushes can be very easily removed by means of a small water-colour brush. The print being completed, it is finally hung up to dry, or better, pinned down to a board where it cannot curl,

being covered with a piece of soft paper in order that dust may not fall upon it while the ink is still soft.

#### Softened Inks and their Pictorial Use.

From what has already been quoted from M. Puyo's practice it will be clear that the addition of a softening substance to the ink is frequently useful in accentuating portions of a print or in reducing contrasts. It will be remembered that a print having been inked with an ink exactly suited to it, the tapping movement as it is proceeded with gives it first a very granular deposit with incomplete rendering of the subject, the grain becoming finer as the picture "develops." These two final results should be obtained at the same moment, but it may frequently happen, if the ink is softer than it should be, that the grain has become fine before the subject is completed, and the tapping action has to be continued in order to obtain detail. For example, in a portrait in which the face is to be accentuated at the expense of the clothing, full detail is required in the face, whilst that in the clothes is required to be subdued. The head is therefore inked with a rather hard ink, the quality of which is compensated for by careful hand manipulation so as to obtain plenty of vigour. The contrasts are further accentuated by a light sweeping movement given by the hind's-foot brush. On the other hand, the clothing will be inked with a brush slightly charged with soft ink, the tapping being stopped before all the details have appeared. The background is also treated in the same way. Thus, by using a soft ink it is easy to produce an effect similar to that of over-exposure, and the process is useful for subduing details, with the difference that while in other photographic processes over-exposure involves a number of dark tones, the larger or smaller charge of ink on the brush can be used to regulate the intensity.

The softening agents can be mentioned in three classes:—

1. Copper-plate ink and thin varnish.
2. Mineral spirit.\*
3. Driers, Haarlem drier, Robertson medium, Hamel copaline.

The copper-plate is used chiefly at the commencement of the process, being added in increasing quantity to the litho. ink until the print takes the mixture. The proportion of copper-plate ink may vary according to the exposure of the print and with the different kinds of litho. ink. Such a mixture which M. Puyo calls normal ink having been obtained, further additions of varnish or mineral spirit must be carefully made since their effect on the ink is considerable. As a rule one brush should be kept for a normal ink and another for those of greater softness. Too great an addition of the softening substance can be corrected by the addition of litho. ink.

Mineral spirit has the property of making the litho. ink pseudo-fluid, but in proportion as the spirit evaporates the ink returns to its former state. Secondly, while the softening due to copper-plate ink or varnish remains the same, that given by the spirit disappears, the ink soon returning to its first degree of hardness. This property of the mixture of ink and spirit makes it useful in certain cases, as, for example, in treating a face which is harshly lighted. By following the first normal ink with one containing spirit, the side of the face, which may be too strongly lighted and without gradation, may be given its proper detail and contrasts. The use of ink containing spirit is very similar to the development of a Fresson or Artigue print in a broth of wood powder. The stages of the process are the same, the outline of the image first appearing, next finer contrasts and some little detail, and finally the normal contrasts and full detail. As a general rule, therefore, ink containing spirit may be used—

(a) To diminish the general contrast of a print.

\* M. Puyo does not specify the density or boiling-point of the spirit which he uses, but he probably intends by "mineral spirit" ("essence minérale") the light paraffin oil sold as "petroleum spirit" in this country, and having a density of about .85, and a boiling-point of 120 deg. to 140 deg. F. Petroleum spirit is sold at about 1s. per pint. Motorists might very well employ ordinary Pratt's spirit, which is a very similar liquid to petroleum spirit.—EDS. "B.J."

(b) To obliterate certain parts by converting them into monotone.

M. Puyo estimates that when an ink softened with spirit used, and the normal effect of the negative is desired, an exposure at least one-half of the normal should be given, otherwise a print is obtained with the effect of fog or night.

As regards the driers, their influence on the litho. ink is not so marked as that of the spirit. When commencing work the softening the ink and make it "take," but in consequence of the drying nature the ink becomes glutinous. The hairs of the brush separate into small bundles, each containing several hairs stuck together, with the result that the grain of the print remains coarse. Occasionally this may be an advantage, but M. Puyo cannot recollect developing a print in which it has been so, although it is possible that for certain subjects similar addition of a drier may help the image.

#### The Choice of Methods in the Pictorial Control of Oil Prints.

M. Puyo would not be true to his reputation did he not content, as he does in "Le Procédé Rawlins," on the need of sympathetically treating the print from the negative, and he speaks almost with abhorrence of a photographic impression taken direct from the negative. The four services which the oil process can render the pictorial photographer may be listed as—

1. Accentuation of values,
2. Introduction of dark tones,
3. Introduction of high-lights, and
4. Subduing portions of the image.

The beginner in using the process for the first of these purposes must first bear in mind that the tip of the brush does not form a flat surface on the print, but a spherical cap, so that the brush on being placed on the print first marks a small circle, which afterwards enlarges on pressure. In inking up or over-inking any given shadow, the hind's-foot brush is used without troubling to keep exactly inside the outline of the portion under treatment. The harmonious combination of the portion with the remainder of the image can be easily obtained by drawing the straight brush from outside the region to the dividing line. In accentuating certain portions of a landscape, for example, it is easy to give prominence to detail at one point and to obliterate it at another, either by altering the ink or by varying the method of its application. The latter is usually sufficient. Thus, in order to obtain details in the foreground without altering its tone value, it is treated again with harder ink under the action of which the contrasts gain intensity, and the details spring out. The print is next submitted to the tapping movement applied lightly and sharply, which completes the development and further tends to contrast. A further sweeping movement gives prominence to any foliage in the foreground. The same subject would very likely require details in the distance subduing, for which a brush moistened with mineral spirit is taken, and the distance treated with it. It will at once appear of a uniform grey, and the tapping action can be arrested when the details have sufficiently, but incompletely, returned. Without changing the ink an extreme light tapping action will result in the grain growing gradually finer, the action being arrested when the print is satisfactory in this respect, and before the details have reappeared. M. Puyo in short, briefly summarises his method:—

To bring up detail, hard ink, light continued tapping, and sweeping.

To remove detail, soft ink, very light tapping for a short time and slight sweeping.

In introducing black tones M. Puyo relies upon a refinement of manipulation which allows even dark tones of extreme small area to be accentuated when using a brush of fair size. This follows from the property of the ink to adhere more firmly to the dark portions of the print than to the light, and consequently, a careful adjustment of the tapping action may

then a small area of dark tone, while it has no effect on that portion, and the worker may thus apply this *tour de force* in strengthening the eyes in a face or similar small portion of dark existing in a light portion of the subject. In doing this the print is lightly inked, and, as soon as the ink has been taken, is rather more vigorously treated in order to prevent uninking of the light portions; the strengthening of the dark portion being then carried out as just explained.

After drying the print it is possible to further strengthen the lines of small size by taking a water-colour brush dipped in alcohol spirit, charging it with ink, and allowing the ink to be what dry by using the brush on a porcelain palette; at the point that the print is almost, but not quite, dry, it is applied to the spot to be strengthened. In introducing high-lights it is so to wait until the print has dried for forty-eight hours, or several days, as the ink remains soft for this time. Usually the high-light required is found in a light portion of a print, and means of a water-colour brush dipped in water a slight friction removes the gelatine. M. Puyo, however, prefers to introduce high-lights after complete drying. At this stage, friction with rubber will disclose the gelatine and give a strong high-light. A still stronger may be obtained by using an ink-eraser, which will remove the gelatine and give the white paper.

In subduing portions of the image, two methods, under-inking and the use of a very soft ink with careful tapping, are employed. The former may even be pushed to the point of over-inking, and is useful in certain subjects, such as portraits on a very light ground. The second method, which is more general use, tends to suppress detail in the portion where it is not wanted, and to give an almost uniform tone to the whole. It is based on the fact that if the ink is too soft for the grain becomes fine before the details appear. This is most markedly when mineral oil is used as a softening agent. All that is necessary is to avoid prolonging the tapping or arresting it before the appearance of any detail.

#### Some Miscellaneous Hints.

Puyo gives some hints on the use of india-rubber in producing pure high-lights in the print, not only in definite portions of the subject, but in the form of hatching or cross hatching, a facility afforded by the oil process which is of frequent use in strengthening the composition of a subject.

In treating the sky of a landscape a rather softer ink is used, and then after the print has dried for one or two days any desired gradation can be given to the sky by means of india-rubber or ink-eraser. M. Puyo rightly insists on the reserve with which work of this sort should be done.

Variations in the grain of an oil print may be made by suitably choosing the paper support, whether smooth, medium or rough grain, or in the mode of manipulation. The latter is the most effective, and as has been judged from the foregoing, consists in not pushing the tapping action up to the point of complete removal of the ink. As a rule a light and lengthy tapping gives a fine grain, a short and vigorous action a coarse grain. At the same time, in the latter case, a broader effect is produced, as finer details are not given time to appear. It is often advantageous to give a much finer grain to the distance than to the foreground, and in a portrait a finer grain to the face than to the clothes.

An oil print dries very slowly, and during this operation should be carefully protected from dust. The print should not be put under pressure, and should be covered with a smooth parchment paper. Contact with water vapour hastens the drying of the ink, and it is often convenient, after the print has dried for a day or so, to hold it above the steam from a boiling kettle. It may also be pinned down to a board and exposed to the sun for several days.

The gelatine paper cockles on drying, and should be straightened by placing on a sheet of glass, gelatine side downwards, and drawing over the back of the paper a square edge which is moved with the left hand, while the print is held with the right. The print itself should not be moved.

#### Points of Importance.

M. Puyo emphasises in particular the following points:—

1. Aim to give the print an exact exposure, easily done with the aid of a photometer. In summer light an exposure of 3 to 8 minutes in the shade is sufficient for average negatives.
2. Commence inking with the minimum of ink, obtaining the first picture in a very light tone, afterwards securing vigour.
3. Avoid all force in using the brushes.
4. Do as little as possible in the way of treating a dry print with india-rubber. The most common mistake of the beginner is in placing his high-lights all over the picture.

## ORIGINAL METHODS OF TONING DEVELOPED PHOTOGRAPHIC PRINTS.

The following article in the "Scientific American" describes a variation of and an adjunct to the toning of bromide and light prints by the sulphide process, which is particularly worthy of attention now that these methods are so largely employed.—Ems. "B.J."]

The desire to obtain colours other than those given by development *per se* has led the manufacturers and users of bromide so-called gaslight papers to resort to different methods. Many methods used, the one that has found the greatest vogue is the so-called sulphide method, of which the developer may be taken as a good example. About ten years ago the writer recommended in one of the photographic magazines a similar method for obtaining sepia colours on lantern slides. Sulphide tones properly made are permanent. Sufficient time has elapsed since their introduction to sufficiently prove this. Facility of production is also in their favour. The tones are, however, not very varied, nearly always some shade of sepia. Experiments to obtain some other

permanent sulphide tone were made by the writer with what appeared to him to be a fair degree of success. It was found when finished prints made on Velox or Nepera bromide paper (I mention these papers because my experiments were confined to them) were immersed in a solution of ammonium sulphocyanide and sodium sulphide, a good purplish tone, very often equal to a gold tone on printing-out paper, was obtained.

The following formula has proved the most satisfactory of any tried:—

A. Ammonium sulphocyanide .....	8 ozs.
Water to make .....	16 ozs. (fluid)
B. Sodium sulphide (crystals) .....	$\frac{1}{2}$ oz.
Water .....	3 ozs.

Following are condensed instructions for its use:—

BATH No. 1.

Solution A .....	1 oz.
Water .....	3 ozs.
Solution B .....	1 drachm.

Mix just before toning.

Immerse the fixed and washed (and perfectly dried) print. The toning action begins almost immediately, ranging through the purple tones first, and then into the sepias.

Allow the print to remain in the toner till the desired colour is reached, then wash fifteen minutes in running water and dry as usual. With the bath at 70 deg. to 80 deg. F., prints will tone in from fifteen to forty minutes; at 90 deg. to 100 deg. F. five to fifteen minutes will suffice; but it is not advisable to use the bath at a higher temperature than 100 deg. F., owing to its softening action on the film. Prints developed with Velox N. A. developer tone quicker than prints developed with ordinary developer.

The rapidity of the toning may also be increased by adding more of solution B but not more than one drachm should be added to the original solution at one time, as this would render the bath too alkaline and soften the film. It works best when freshly mixed and after forty minutes or so more B solution may be added. The old bath may be kept for future toning, but before use it should be filtered or decanted to remove the white precipitate formed, and fresh B solution added, but it should be discarded when it becomes so alkaline as to affect the film.

It will be found that the toning is influenced somewhat by the character of the negative used, different degrees of density in the negative affecting the silver deposit on the print and the subsequent action of the toning solution. It will also appear that matt papers tone more readily than the glossy, and that purple tones are easiest secured on glossy papers. It must be confessed that the laws governing the action of this bath are not as thoroughly known as could be desired. Sometimes it will work quite rapidly, and again, under apparently the same conditions, it works much slower.

An Alternative Formula.

Further experiments have shown that its certainty of action could be greatly improved by mixing with it hypo alum toning solution, made according to the following formula:—

C. Hypo .....	10 ozs.
Water .....	50 ozs.

Heat to boiling and add

Powdered common alum .....	2 ozs.
----------------------------	--------

Allow to stand until cold. It improves by standing.

Bath No. 2.

A .....	$\frac{1}{2}$ oz.
C .....	$\frac{1}{2}$ oz.
Water .....	3 ozs.
B .....	1 drachm.

When B is added the solution is clouded by the precipitate of aluminium hydroxide. This precipitate does not interfere with the toning action.

This latter bath (No. 2) yields tones equal to and quite superior to the former bath (No. 1).

It also smells more strongly of hydrogen sulphide, and is not advisable to use it where the ventilation is poor. The action ceases more of B can be added. The latter bath yields better lasting qualities. I have known it to tone without the addition of an additional quantity of B after it has stood over-night.

An Improvement to Sulphide Tones

Prints from some negatives when bleached and redeveloped with sulphide solution sometimes incline more to the red than is desirable. Having ascertained this fact, colder tones can be obtained on subsequent prints to be toned by using bath No. 1 as a preliminary bath. How long the print should remain in bath No. 1 cannot be stated with exactness, as there are many factors to be taken into consideration; chief among these are (1) how much the colour given by the bleach and redevelop method differs from the desired colour; (2) how fresh the bath is. The fresher the bath the quicker it works. Other things being equal, the longer the print remains in bath No. 1 the colder the tone. In a freshly-prepared bath at the ordinary temperature even fifteen seconds is enough to effect a change in the finished print.

As a general thing, any immersion—even one falling far short of the time necessary to produce a visible effect—is quickly apparent by the print refusing to bleach as much as it has done were it untreated when placed in the bleaching solution. Prints should be well washed before placing in the bleaching solution, and should remain in it from five to ten minutes or until it is certain that the bleaching is completed. After bleaching, prints should be rinsed free from bleaching solution and redeveloped as recommended in the Velox developer instructions.

What chemical reactions take place in what I would call the sulphide sulphocyanide method of toning I have not investigated far enough to state.

However, hydrogen sulphide is released, and this in its condition no doubt has power enough to attack the silver image. It is also certain that other reactions have an effect, for if the ammonium sulphocyanide is replaced by an equal weight of the potassium salt the toning action is very slower.

To the question, Why does this method give a different result from that obtained by simple bleaching and re-developing with sulphide solution? it might be answered: Because the conversion of the silver is not so complete as in the latter process. In my opinion I would say that it would be hard to imagine the colours obtainable on some prints as resulting from a combination of sepia and black.

As they are, the processes described are practical, but there is much room for improvement.

MILTON B. PUNNETT

THE BIRDLAND LECTURES.—At this season of the year, when the majority of society secretaries are seeking interesting subjects with which to fill their programmes for the forthcoming session, the "Birdland" booklet comes as a timely reminder that at least one evening may be spent with both pleasure and profit by securing the services of Mr. Oliver G. Pike, whose "Birdland" lectures, illustrated with both lantern slides and the cinematograph, never fail to draw an appreciative audience. Mr. Pike is now filling up his winter list of engagements, and those desirous of securing his good services should make early application for terms and vacant dates to Messrs. Sanders and Crowhurst (Dept. T.), 71, Shaftesbury Avenue, London, W.

"TAQUA" DEMONSTRATIONS.—A new model of the "Taqua" camera for producing circular pictures on ferrotype plates is now on the market, and Mr. Jonathan Fallowfield announces that the camera can be seen and practical demonstrations given at any time between 3 and 10 p.m. at "Pastimes," 51, Strand, London, W.C.

BRISTOL PHOTOGRAPHIC CLUB'S EXHIBITION.—The judges will be Mr. F. M. Sutcliffe (pictorial) and Mr. Abel Lewis (technical). There will be no entry fees, except a registration fee of 1s., which will entitle the exhibitor to a number of exhibits, and in order to prevent overcrowding of the exhibition rooms there will be a Selection Committee, consisting of Mr. John Fisher, Mr. Percy Lewis, and Mr. Fred Marsh. All exhibits, whether selected or not, will be passed before the judges.

## THE STUDIO AND ITS BLINDS.

THE present article, like a former one on "Studio Construction," suggested itself from the queries replied to in the "Answers" columns of the "Journal." It will be the object here of the writer to give a few practical hints that may possibly be of service to those of limited experience. It should be obvious to everyone that no set rules can be laid down for lighting a studio, as so much must necessarily depend upon its aspects and form, as well as upon its surroundings.

One of the most frequent queries seems to be with reference to stopping out the sun. There are some studios so situated that the sun gives but little trouble at any time. For example, we may have one that runs north and south, and the south end abuts on a high building. Here the sun will give but little trouble at any time of the year. A plan that fulfilled this desirable condition was at one time in vogue: it was to have a large sail fitted outside the southern end or side of the studio, which could be hauled up or let down at pleasure. Another method is to have a permanent wooden hoarding, painted black outside, which prevents the direct rays of the sun from reaching the studio. Both these contrivances are very efficacious, but they are a little costly, as they must be substantially fixed to resist strong winds. They are also somewhat unsightly, when seen from the outside. Should the sun cause trouble only during two or three months of the year it may usually be overcome by fitting inside, temporarily, a curtain of dark colour, say black, over that portion of the roof upon which it shines, and which can be readily removed when it has moved off. In some circumstances this might possibly entail stopping out light which it is desirable to utilise. In that case the glass may be stippled over with flour paste, with which some common whiting has been mixed. This will stop out the glare of the sun while yet admitting light, and can be easily cleaned off at the end of the summer.

### Obscuring the Studio Light.

Another good plan of subduing direct sunlight is to cover that portion of the roof glass upon which it shines, either with tissue paper, or, better still, architects' tracing-linen. This can be strained on light wooden frames, which may be made to slide backward or forward, or be removed altogether when the sun ceases to be troublesome. Or the tracing-linen may be fitted as a blind on a spring roller, to be drawn down or let up as desired. Tracing-linen, which is by no means expensive, may be had from any of the dealers in artists' materials. It stops off but little light, while it quite subdues strong sunlight. Should the aspect of a studio, lighted from one side only, be such that the sun when shining is on it, more or less, all the year round, it is a good plan to have it glazed with ground glass when it is built. Ground glass when clean stops off but little light, but in large or smoky towns it is prone to get dirty; it then shuts out a considerable amount of actinic light, but soap and water will quickly remedy this defect.

### The Colour of Blinds.

A query one frequently sees has reference to what colour the blinds or curtains should be, and how they should be arranged. As a matter of fact, the colour, *per se*, is quite immaterial, so long as the material is sufficiently thick or opaque to arrest the light and enable the sitter to be lighted so as to obtain proper chiaroscuro. But the comfort of the sitter is a consideration. A glaring light, such as would be caused by white blinds, would be trying to their eyes, and for that reason is not conducive to a natural expression. Blue or green both yield a soft and quiet light that is very pleasant to the eyes, and therefore very suitable. Buff might be used, but on the whole the writer much prefers either one or other of the first-named colours. Black might be used in studios where the light is very strong, say, one with a south aspect, but it gives the studio a sombre and somewhat funereal appearance, which is likely to have a depressing effect upon a sitter. With a south-lighted studio, blinds or curtains of thick material, either dark blue or green, are far preferable to black, as they will effectually produce all the shadow that may ever be required.

For the roof either blinds or curtains may be employed. If the former, they are more convenient to use if they are on spring rollers, fitted quite close to the ridge of the studio, so that they can be drawn

down or let up as required. If curtains are used they are best fitted to run horizontally on wires, and in sections, which overlap each other. The fabric should be a soft material, such as thin serge, with small brass rings sewn at short intervals along the edges. These are threaded on wires, running from end to end of the studio. The curtains should hang rather full, and, as just said, overlap one another, the laps being upward, so that no light passes downward between them. Should the roof of the studio be large, it is well to have the curtains in four sections; if small, three will suffice. The curtains are manipulated by simply pushing them to or fro with

a light bamboo rod. In some studios where the sun gives trouble two sets of these curtains are fitted, the one next the glass white, and the other of a dark colour. With this arrangement the light is under perfect control in every way. The wires must be strained tight and kept taut, otherwise the curtains will not run freely. The wires may be kept taut in the same way as they are in wire fencing, and screw fittings for the purpose may be had at any of the large ironmongers. For the wires iron should be avoided, as it rusts so quickly, and then the rings will not pass freely, and, moreover, if water should happen to get through the roof, the iron rust would stain the curtains. Stout copper wire—say No. 12, B.W.G.—is about the best for the purpose.

### Side Studio Curtains.

For the sides of the studio either blinds or curtains may be used, but it is desirable that they be capable of regulation alike from the top and bottom. Therefore they should be in two parts—one on spring rollers fixed a little below the skirting, so as to be drawn up, and the others on rollers near the eaves to pull down; in this way the side light is brought under complete control. Spring blinds are a little costly, but every purpose is served by having curtains in two parts, running on rods or wires; the lower portion reaching from a little below the skirting to about the middle of the side, and the upper ones from the eaves to somewhat below the top of the lower ones. If the side curtains are in one piece they can, to an extent, be stretched somewhat diagonally; but, on the whole, it is best to have them divided into two portions, particularly if the side is high, as then the light is under more complete control. The material for the side blinds may be similar to that of the roof ones. Two sets may be fitted—the one white and the other dark—but this is rarely necessary, except where the sun is on the studio for a good part of the day. With a direct south aspect two sets are certainly very desirable.

### Colours for Studio Wall Coverings.

With regard to the colour for the interior of the studio, the comfort of the sitter is the main consideration. The late Mr. Adam Salamon, to whom reference was made in the former article, had the sash-bars and much of the other parts of the studio painted a dark chocolate colour, and at his time many photographers in this

country followed his example. The object of this was to avoid all traces of reflected light. Personally, we are not much in favour of this colour. We prefer a dark French grey or a neutral tint for the sash-bars, and a lighter French grey for the interior of the studio generally. This gives a cheerful appearance to the place, and is comfortable to the eyes of sitters. If the studio be of the lean-to form and the side is of the matchboarding it may be painted a medium

French grey, or greyish green. These colours, while comforting the eyes of sitters, tend to reflect a light that aids materially in softening the shadows of the portraits. If the side should be a wall it is better to have it papered with a paper with an unobtrusive pattern, with the ground of a similar tint to the above. The paper will give the side of the studio a better appearance than if it were simply plain paint.

WM. MICHELL.

## THE PFUND PHOTOMETER.

[The reference by Mr. R. J. Wallace recently to the simple type of photometer designed by Mr. A. H. Pfund having brought us several inquiries, we applied to Mr. Wallace for the text of the original description of the instrument in the "Johns Hopkins University Circular," 1906, No. 4, in kindly sending us which Mr. Wallace writes: "To avoid the formation of oxide by exposure to the air, I would suggest that the mirror surface be flowed over with (or dipped into) a thin collodion. Otherwise the tarnishing of the silver would make a comparable density of measurements impossible."]

THE form of photometer about to be described is not to be considered as an improvement upon the well-known Lummer-Brodhun type, but rather as a simplification. During the course of certain optical investigations, in which it becomes necessary to make photometric measurements, the use of a Lummer-Brodhun photometer becomes impracticable, either on account of its bulkiness or on account of the angle which the two beams of light whose intensities are to be compared make with one another. It occurred to me that a photometer, which was both simple and accurate and which could be made

the eye or telescope on the edge of the silver, it is easy to cause the line of demarcation between the two fields to disappear. The method of using the photometer is shown in Fig. 1, in which  $s'$  and  $s''$  are the two sources whose intensities are to be compared, and  $P$  the photometer.

In addition to its simplicity and compactness, the other advantage claimed for this photometer is that it can be used under all conditions of angle which the two beams whose intensities are to be compared

Fig. 1.

to fulfil any requirements which the experimental conditions might demand, could be made in the following manner:—

A piece of plate glass, about 2 mm. thick, is silvered, highly polished, and then cut in two, the diamond scratch being made on the "glass," and not on the "silver" side. If the break is not perpendicular to the flat surface, that portion of the mirror is selected which has an acute angle at the edge of the silvered surface. Upon close examination it is found that the silver extends up to the very edge, and hence, by using this arrangement as a photometer and focussing

Fig. 2.

make with one another (with the exceptions, of course, of absolute normal and grazing incidence). This fact is brought out by Fig. 2, in which  $a_1, a_2$  and  $b_1, b_2$  respectively are the sources of light. A photometer of this kind has already been used in a determination of the distribution of light in the various spectra of a grating\*, and has yielded very excellent results.

A. H. PFUND.

## THE GENESIS OF A MODERN LENS.

[The following second portion of an article by Herr L. Büniger in manufacture and design of a high-class modern lens, a subject which may, nevertheless, be made, as in the present instance, of interest to

THE discovery of the Fraunhofer lines, and the consequent determination of the optical constants of a glass, enabled the mathematician to select glasses from the catalogues of the smelters which would be suitable for his purpose. An important question then arose as to whether he could use those in existence or whether it was necessary to find absolutely new types. Schott and Abbe's work was here of enormous importance.

When a new type of lens is to be made, approximate values are first found analytically, and the correction of these is effected with trigonometrical formulæ, which render it possible to trace exactly the path of a ray through a lens combination.

First of all a ray of light, parallel to and very close to the axis, is taken, and followed from surface to surface to the point where it cuts the axis of the lens. If the lens is symmetrical—that is, con-

sisting of two halves of absolutely identical properties—it is sufficient to calculate one-half only, and usually that behind the diaphragm is chosen—both halves are, as a rule, separated by a stop midway.

The first calculation is for the D line. Then the same ray is calculated for F. A comparison of the final results gives an idea of the chromatic correction of the centre of the objective. Each calculation gives in a certain measure two results—the back and the true foci of the ray. By the back focus is meant the distance between the last surface of the lens and the point where the ray cuts the axis, whilst the true focus is reckoned from the nodal point of the system. The nodal points as a rule lie within the system—that is, in the glass.

When the calculations for two rays for the centre are completed, the back focus of the two rays must, if the result is to be satisfactory,

the same numbers. This also applies to the true focus. In the back focus cause coloured halos or rings, whilst focal produce images of different size. If the correction is to be the results must coincide with great accuracy, and the errors do not exceed 1.50 millimetre (equals 1-1250 inch). That this of correction is not attained in a trice is obvious, and the and the thicknesses must be altered till the results are satisfactory. It may be mentioned that the corrections are usually made aid of logarithmic tables, and are usually taken to five places after to seven places of decimals. The more lenses and radii em has the more wearisome is the calculation.

us assume that the centre of the system shows equal back and for the two colours, D and G. This condition is called le achromatism."

order to correct an image for spherical aberration a ray parallel the axis is calculated out. The height of the incidence of this determined by the ratio aperture of the lens. We follow by ble formulæ this marginal ray through the lens combination obtain by calculation again the values for the back and true The calculations are made first for the D line. If the back or D on the axis and D in the marginal ray coincide the spherical ation for D may be considered obviated. If the true foci of axial D and the marginal D coincide distortion is corrected. is a happy case which rarely occurs from the first calculation, therefore various other calculations, alterations of the radii and nesses, etc., are necessary. The same ray is now calculated out, and the results compared with the previous ones. If the foci and true foci for axial G and marginal G coincide, then spherical aberration and distortion for G are corrected. If the foci for G and D are coincident, then the well-known Gauss ion is fulfilled. A comparison of the foci of the marginal rays and G gives the measure of the colour enlargement at the

When the mathematician has corrected the lens up to this the state of correction is that shown by good aplanats, and is with which one was previously satisfied. That these calcula- are hedged round with difficulties will be recognised when it embered that any change of the radii, etc., to obviate spherical ation can absolutely upset again the chromatic aberration in ntre.

us assume, however, that the correction of the back and true or D and G for the centre and margins is perfect. Our next on is to determine the zonal aberrations. The difficulties here se the more precisely we understand this word. Let us be ed, however, by placing the point of a compass in the optical and with half the radius of the lens aperture describe a circle the axis.

order to obtain an idea as to the condition of correction of the we calculate out a ray for D and G parallel to the axis, and istance from it equal to half the radius of the aperture. The rison of the focus and the back focus of these two rays with

the previous results gives the desired result. Unfortunately, it is not possible to give exactly equal foci and back foci to all these rays, but the calculator must try to reduce the errors to a minimum, which can naturally be much more easily done than with a single lens.

One must always try to reduce one error at the cost of another. The correct medium must be left to the experience of the calculator.

Now let us turn to treat, in general terms and briefly, of the correction of astigmatism. For this purpose we assume that every point in an object sends individual rays to all points of the lens, and forms a cone of light. the circular base of which corresponds with the surface of the first system, whilst the apex of the cone is in the object itself. According to the position of the latter the light cone is more or less distorted, and is only completely regular when the object point lies on the axis. An exact point-like formation of the rays proceeding from a point is only possible when all the rays proceeding from a point are again united to a point after passing through the lens. Thus all the bundles of rays from the points of the object, so far as they lie within the angular aperture of the lens, must be again united into points, and they must all lie on one plane. The smaller the aperture of the lens or the smaller the stop the nearer will this ideal condition be approached. For the same reason it will always be found that lenses with relatively large aperture suffer from a certain want of definition, though several define sharply with full aperture

To return, however, to our calculations, it is essential to determine the astigmatism for three rays of the above-mentioned beam—the principal, the meridional, and the sagittal ray. The accurate position of these it is unnecessary to define.

These three rays are again calculated for the two colours D and G through the lens combination, the radii and thicknesses altered till taking all the results together they are satisfactory both for chromatic and spherical aberration. That this work is extremely tedious and difficult, requiring great care and patience, will be clear to the laity from what has been said, and no one will be surprised to hear that the calculations for some modern anastigmats have lasted for a year.

The greater the angle for which astigmatism must be practically removed, the more difficult becomes the calculation, and the more zonal errors are met with. Most of our anastigmats are corrected anastigmatically over an angle of 60-70 degrees.

An excellent means of compensating for error lies in placing opposite to one another two identical half systems. By the symmetrical opposition of two identical series, distortion and spherical aberration beyond the axis are *a priori* destroyed, which is not the case with nonsymmetrical lenses. Further, a well-corrected symmetrical objective has the advantage that one of its halves can be used, generally with somewhat smaller stops, as a single landscape lens.

LUDWIG BUNGER.

(To be continued.)

## ESTIMATING INCREASED EXPOSURE REQUIRED WITH COLOURED FILTERS.

The following short paper appears in the "Photographic Journal" for August in continuation of the report of the demonstration given by Mr. McIntosh recently before the Royal Photographic Society.—Eds. "B.J."]

estimating the opacity of the filter it is neither necessary nor desirable to use a coloured object, since the presence of colour would introduce confusing factors. One or two methods of making such are in common use. One is to expose half of a plate without a and the other half through a filter upon some half-tone picture black and white, say upon a platinum print, giving a longer exposure to the second half. The result will confirm the estimate of opacity of the filter, or show it to be wrong, in which latter case a test must be made. The method is capable of giving accurate results, but is wasteful of time and plates.

Another method, occasionally used, is to expose an actinometer, a Watkins' or Wynne's, to daylight, noting the time taken by sensitive paper to darken to a certain tint. A second exposure is made through the filter, and the time taken as compared

with the first exposure is a measure of the opacity of the filter. Apart from the difficulty of observing the tint through the filter, this method cannot give accurate information, as the colour sensitiveness of the paper cannot be identical with all the plates on the market, and may not be identical with any. At its best the method can but give a very rough approximation to the information wanted.

The method I recommend is to photograph an evenly illuminated sheet of white paper through a graduated transparency, which is easily made and may be used at any time.

To make the scale it is convenient to expose a half-plate (not necessarily an orthochromatic plate), upon a sheet of white paper. The shutter of the dark slide should be fully drawn, and a brief exposure, say 1-64th of a second, given.

The shutter is pushed home half an inch and a second exposure of

the same duration is given. The third section of the plate should receive 1.32nd, the fourth 1.16th, the fifth  $\frac{1}{8}$ , and so on. When twelve exposures have been made the ratio will be 1 to 2,048. Development should not be carried too far, in fact, so long as the steps are clearly marked, the thinner the negative the better for the purpose.

Out of this half-plate we have to cut a piece quarter-plate size, but with its length across the half-plate so that the steps run the long way of the plate, and it is desirable to select that portion of the half-plate which has a clear (or nearly clear) glass strip. We shall have on the width of the quarter-plate six grades, with a ratio of 1 to 32, which is amply sufficient.

This scale is placed in a quarter-plate dark slide with the glass side towards the lens; a plate of the brand with which the filter is to be used is then placed face down on the scale. The dark slide being placed in the camera, the lens is directed to the sheet of white paper. The shutter of the slide is drawn, say three-quarters of an inch, and an exposure is given without the filter; probably one second in a good light with  $f/8$  will be sufficient. The shutter must then be closed and the dark slide removed from the camera. A slip of blackened cardboard has to be fixed in the reversing back of the camera in such a way as to shield the section of the plate just exposed. The dark slide is returned, the filter placed in position, and the shutter being drawn a quarter of an inch or so at a time, a series of exposures are given to the plate. Each exposure must be the same as that given without the filter (not multiples of the exposure as when the scale was being made). The last exposed section of the plate will have had one unit of exposure, and the other sections 2, 3, 4, 5, and 6, and so on.

When a print is being made from this negative, the section exposed without the filter is compared with those given through the filter, and it is a simple matter to decide how many times exposure the filter requires.

It will be obvious that the tests may be made without the scale, and for all ordinary purposes the results will be accurate enough, but it must be remembered that the filter may have a considerable effect on the gradation. A violet filter, as used in three-colour work, for example, may reduce contrasts, and an orange or red filter may increase them. If such should be the case, the use of the scale will indicate it, and the exposures may be shortened or lengthened as seems desirable.

J. MCINTOSH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, AUGUST 30.

Aberdeen Photo Art Club. Annual Business Meeting.

SATURDAY, AUGUST 31.

North London Photographic Society. Outing to Golder's Hill.  
Handsworth Photographic Society. Excursion to Rednal and Oratory Retreat.  
Coventry Photographic Club. Outing to Berkswell and Hampton.  
Aberdeen Photo Art Club. Outing to Crathes.

MONDAY, SEPTEMBER 2.

Bowes Park and District Photographic Society. "Enlarged Negative-making."  
E. H. Down.  
South London Photographic Society. "A Little Light on Lenses." Dr. A. R. F. Evershed.

TUESDAY, SEPTEMBER 3.

Royal Photographic Society. Ordinary Meeting for the Election of Candidates for Membership only.  
Hackney Photographic Society. "Flower Photography." A. D. Fort and A. J. Linford.

WEDNESDAY, SEPTEMBER 4.

North Middlesex Photographic Society. Lantern Slide and Print Competitions.  
Everton Camera Club. "Development." J. Mansell.

**SOUTH MANCHESTER PHOTOGRAPHIC SOCIETY.**—The exhibition of the above society will be held on February 20, 21, and 22, 1908; closing date for entries, February 5. Further particulars may be obtained from the secretary, Mr. M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made by August 12 and August 17:—

**TRANSPARENCIES.**—No. 18,271. Improvements in photographic transparencies. Lawrence Dalton Whitfield, c/o Paget Prize Company, Ltd., St. Albans Road, Watford, Herts.

**SIGHTING OBJECTS.**—No. 18,388. Improved device for indicating correct direction for sighting objects to be photographed. Muschke, 116, High Holborn, London.

**APPARATUS.**—No. 18,399. Improvements in or relating to graphic apparatus. Georg Bruno Seele, 111, Hatton Garden, London.

**CAMERAS.**—No. 18,430. Improvements in photographic cameras. William James Lancaster, 24, Temple Row, Birmingham.

**DRY MOUNTING.**—No. 18,526. Dry mounting attachment. Hyde, 30, Duke Street, Chester.

**MAGNESIUM LAMP.**—No. 18,584. Appliance for use in burning magnesium ribbon or wire for photographic and other purposes. Edward Albert Marr and Johnson and Sons, Manufacturers Chemists, Ltd. (1882), 4, South Street, Finsbury, London.

**PRINTING FRAMES.**—No. 18,600. Improvements in photographic frames for copying plans, drawings, and the like. Richard Baker and Philip William Jones, 156, Llandaff Road, Cardiff.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CATATYPE PROCESSES.**—No. 29,480. 1906. The invention consists in a process for imparting permanent catalytic properties to a print, toned with platinum (treatment with ammonia gives only temporary powers of this kind). The print is treated with oxidising agents, such as potass permanganate in acid or alkaline solution, ceric sulphate, chromic acid, or a bichromate or acid, a persulphate in alkaline or acid solution, and with ammonia or the ammonium salt of a feeble acid. The treatment with ammonia or an ammonium salt may accompany that with the oxidant if it does not produce any injurious effects—that is to say, for example, in the case of permanganate and persulphate. Otherwise the oxidising agent is allowed to act first, and then ammonia or ammonium salt. In cases in which the oxidising agent forms a precipitate that has a powerful catalytic action upon hydrogen peroxide, the precipitate must be removed. For instance, when potassium permanganate is used, the negative is treated with a solution of oxalic acid, to which may be added a substance, for example, alum, capable of hardening gelatin. A bath of this kind for removing the substances that hinder catalysis, is composed, for example, as follows:—

Potassium permanganate .....	10 gms.
Water .....	100 ccs.
Normal ammonia solution .....	100 gms.

After about ten minutes, the picture is removed and washed in a 1/20 normal ammonia solution. It is then immersed in a bath composed of a mixture of equal parts of a saturated solution of oxalic acid and a saturated solution of potash alum, washed with water, and dried.

The process may be applied to all platinum pictures which have been produced from silver pictures by treating these with a solution that contains, in addition to alkali platinous chloride, substances which produce an acid reaction of the bath. The presence of alkali chloride is advantageous, as is also that of substances which harden gelatine, and particularly those of the alum group.

of course, it is necessary to avoid the presence of substances that hinder the reaction of the silver with the platinum toning bath, such as, for example, sulphur compounds like potassium sulphocyanide or sulphocarbamide, and mercury compounds. The presence of hydrogen ions is essential.

If the platinising is effected with a bath containing these ions, then the platinum pictures produced can be made applicable for reproduction by catalysis. A. G. Bloxam, for the "Neue Photographische Gesellschaft," Steglitz, Berlin.

**BACKGROUND.**—No. 21,781. 1906. The claim is for a method of photographing subjects against any desired background by using a transparency of the latter in contact with the plate, but by daylight. In other respects the processes is similar to that of Dischner ("B.J.," June 15, 1906, p. 4727). After the object has been photographed in the ordinary manner against a dark background, this background is replaced by one of a light tint, and daylight shut out from the object by means of a dark carpet or curtain, which, resting on the extended wires, is pushed over the object like an open tent. The curtain is drawn so far forward that light from above, as well as from the sides, is shut out from the object, whilst light coming from above on to the back is admitted for illuminating the light background, which, for the purpose of better intercepting the light, may be placed so as to slant backwards. The transparency has been simultaneously arranged in front of the plate and the second exposure takes place, the object appearing dark on the light background. Hans Frederik Immanuel Mohr, No. 21, Kongensgade, Copenhagen; and Joseph Vincent, No. 7, Palagade, Copenhagen.

**RY SURFACING OF PHOTOGRAPHS.**—No. 5,413. 1907. The invention consists of a process and a machine for the surfacing of photographing gelatine prints, in which the material is pressed upon a band of celluloid, sheet metal, prepared fabric, or the like, travelling in the direction of its length, and having a surface giving the desired effect, and the band, with the picture, is then passed into a drying chamber in which the pictures are so dried that they part from the band and can be removed. Benno Bzykowski, 25, Winterfeld Strasse, Berlin.

**ON MAGAZINE CAMERA.**—No. 28,305. 1906. The camera provides for the exposure and development of a large number of circular plates for disc or button photographs. Certain novel movements are provided for handling the plates. The cap *i* being removed, together with the rod *l*, spring *o* and follower *p*, the sensitised

Fig. 1.

plates *q*, which, if not opaque in themselves, should be properly backed, are placed in the tube or magazine *c* to the proper number with the sensitive surfaces towards the lens, and the

Fig. 2.

ing follower inserted in the manner shown in Fig. 2. The foremost plate then rests against the gate *t*, which is normally pushed in to the full extent. The gate is then withdrawn by

pulling out the rod *u*, as shown in Fig. 1, when the foremost plate is pushed forward by the follower until it rests against the shoulder formed by the ring *s*. The lens is then uncovered to make the exposure, when the rod *t* is pushed in, which causes the gate to push the exposed plate laterally from the magazine in the runway *v*, when it rolls downwardly into the bath receptacle *y*, which is then placed beneath the mouth of the runway.

The receptacles *y* are each made of a size to enable them to hold an indefinite number of plates, and each is intended to contain a combined developing and fixing bath. When a predetermined number of plates have been exposed and deposited in the bath, the bath vessel *w* is rotated upon its axis a distance of one notch, which causes the receptacle containing the fixed plate or plates to be moved outside of the case. The plates are then removed, and the operation repeated until the magazine is exhausted. When this occurs the follower *p*, which is thicker than a plate, will rest against the ring *s*, and the gate, being withdrawn, cannot be returned until the follower is removed to refill the magazine. Louis Mandel, 146, Lytle Street, Chicago, U.S.A.

**CHANGING BOXES.**—No. 28,543. 1906. The invention relates to change boxes of the type in which there is an adapter, which may be separated from or form part of the camera, and also an inner container for daylight loading, comprising telescopic parts with means for changing the plates from front to back, the present improvements consisting of the combined arrangement of parts, and new form of adapter, container, and mechanism for changing and actuating the plates. The fifteen figures showing details of the apparatus are necessary for the understanding of the construction and working of the changer. Fred Hilton and Arthur Brown, 52, Taunton Road, Leò Green, Kent.

## New Trade Names.

**RELIABLE.**—No. 292,467. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including paints and varnishes, and not including any goods of a like kind to any of these excluded goods. W. B. Fordham and Sons, Ltd., 36 to 40, York Road, King's Cross, London, N., manufacturers. April 25, 1907.

**WHISTLE BRAND.**—No. 294,697. Chemical substance used in manufactures, photography, or philosophical research, and anti-corrosives. P. Germain and Cie., 11, Rue du Milieu, Petit-Ivry (Seine), France, manufacturers. July 18, 1907.

MR. WALTER PILLEY has presented to the Herefordshire Photographic Society a solid silver tankard, to be competed for annually. Herefordshire pictures only are eligible.

**PICTURE POSTCARDS IN BLACKPOOL.**—The centre of the picture postcard world at present is Blackpool. A fine was inflicted there last week on a local postmaster for street obstruction, the evidence showing that people were driven off the footwalk owing to the number of men and women standing outside the post office industriously writing picture postcards—presumably to their friends at home. A witness said he saw postcards being written on the post box, on the office windows, on the table, on every available ledge, while frequently the writers' hands and, in one instance, the back of a friend who obligingly stooped for the purpose, were utilised as desks. Possibly an explanation is afforded by an amusing communication which the "Manchester Guardian" has received from a correspondent as to special postcards, which are being sold in Blackburn for the good folk of that great weaving town who are staying at home, while their more fortunate friends are on holiday. "One of these cards," says the correspondent, "represents a pair of clogs, bearing the unkind motto, 'To think tha'll ha' to come back to these!' A postcard with a photo of reedhook, scissors, and shuttle is inscribed, 'Ye'll be glad of us afore so lung.' But perhaps the most unfeeling card of the series is one which shows a pair of clogs and bears the words, 'Nob'dy ud think, to see thee neaw, as tha wears these a-whom.' The Post Office authorities state that Blackburn folk away on holidays have posted 200,000 postcards home. It is evident that those who remained at home have been 'getting their own back.'"

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Reducing Sulphide Toned Bromide Prints.

A correspondent, writing to "The Photographic News" with reference to the above subject, says: My method of reducing a sulphide toned bromide print is to place it in a hypo-alum bath, and heat it in the same manner as one would an untuned bromide. I have found this satisfactory in every way, and the colour is, if anything, improved.

### Handles for Hand Cameras.

Writing of camera handles in "Photography," Mr. Charles H. L. Emanuel says: "It is certainly a moot point whether the ordinary flexible leather handle is a useful form, and yet it is universally found with a hand camera. The one great difficulty of a hand camera is to give sufficient exposure without the risk of vibration; and there are many persons who, with their present apparatus, the whole gripped tight to the chest, cannot safely expose for the fifth of a second. Put a much steadier hand at architectural or street scene work, where the camera has to be held up by means of a wobbly leather handle, and it is a question whether his perpendiculars will be right or the result free from evidence of vibration. An absolutely firm handle would be of great assistance in such a case, and would be most convenient if made of aluminium, broadened in the centre for the purpose of grip, and hinged with a spring, so as to lie down for convenience in packing for travel.

### Above All, Patience.

"You are old, Father William," rose to my lips (writes the "Magpie," in "The Amateur Photographer"), as I listened to the recital of a new and, of course, improved printing process which has been, I understand, brought out by Mr. Welborne Piper. I may be—according to some people, I must be—wrong, but, as far as I can at present understand, "Bromoil" is calculated to make amateur photography, if not impossible, at least improbable. To obtain a pictorial something, the amateur must first learn to excel in bromide enlarging, in "ozobrome," and in the "oil pigment" process. Having taken these preliminary steps the fun begins. First make a really good enlargement. If you then have the heart to risk ruining it, you gelatine it. Should it survive this, it is ozobromed. So far only twenty-two baths are required, which will not take above four hours. Mostly, however, another couple of hours will be needed for re-bleaching and re-developing. If not spoiled before, the chances are that when pigmenting is undertaken ruin will set in. However, a centenarian may hope to produce a masterpiece with this fascinating intricacy.

### Toning P.O.P.

For even toning (writes Mr. Percy J. Slater in "Focus") it is advisable to tone all the prints at once, when only a few prints are being toned. When dealing with large batches, however, the prints should be divided into two or three lots, and the toning solution divided up in proportion. When toning a large number of prints in one lot of solution, a few at a time, the first few prints usually get evenly and fully toned, while the last few appear either double toned, or under toned compared with the others; but by following the method outlined above, the whole batch of prints will be evenly toned.

It is absolutely necessary to keep the prints quickly moving one over the other in the solution, or toning will take place irregularly. I generally place the prints in the bath face downwards, and quickly turn them over face upwards one at a time. They are continually kept moving in this manner until they appear sufficiently toned when looking at the surface, when they are transferred to a dish of water, and then quickly washed in about two changes, to stop the toning action, when they are ready for fixing. As the prints dry considerably colder than they appear when wet, toning should not be carried too far, or the finished prints will appear muddy and lifeless.

## New Books.

"Le Procédé Rawlins à l'Huile." By C. Puyo, Paris. Paris. 1 franc 50.

That M. Puyo has put into writing his practice of the process he gratefully acknowledges to Mr. Rawlins is undoubtedly of no little importance to the class of worker whose aim is in the direction of pictorialism, and who is without scruple methods. There is no doubt that the arrival of the oil process will mark a new era in the so-called pictorial photography, though one's first thought is the aspiration that its facility of will prove the ruin of many a bubble reputation, it is probable that this reason its adoption will be slow. For even when the skill M. Puyo's volume shows to be necessary has been acquired by a practitioner has still to learn everything in the way of using newly acquired powers. But that the process is certain to do the exhibition world there can be little doubt, and therefore have drawn largely on our space this week in order, by M. Puyo's permission, to place his methods before English Colonial workers. Yet we must not allow ourselves to forget the sharp distinction between a print produced by the oil process and those by the older and less elastic processes. Essentially an oil is not photography at all, and the gulf between it and other processes is so wide that we would like to see a new word coined to describe it and others of similar "plasticity." Call a "straight photograph" good or bad as you will, with all its sins upon it, it has redeeming qualities of literalness, and it would be all the better to have another name found for pictures which are actually of a different kind. For M. Puyo, his colleague, M. Demachy, and others who have shown what a process such as that of Mr. Rawlins is capable of in the hands of an artist-craftsman, we have not but the liveliest admiration. It is not too much to say that this piece of original dexterity, M. Puyo's applications of the properties of greasy inks on a gelatine surface to pictorial ends, is pretty an example of genuine craftsmanship as can be found in photographic or other process. Perhaps he dwells in too great on the technique of which he has made himself so proficient a man, but the process has evidently obsessed him, and he is unable to restrain his ardour in explaining the minutiae by which he obtains his results. Our extracts from the newly issued volume, full as they are, do not at all exhaust M. Puyo's descriptions, whilst the several plates in the volume are needed for certain of the experiments.

### CATALOGUES AND TRADE NOTICES.

**PHOTOGRAPHIC LENSES.**—Messrs. A. and E. Staley send us a copy of a catalogue recently issued by the Bausch and Lomb Optical Company, of Rochester, New York, which gives much useful and up-to-date information regarding the various lenses made and supplied by this well-known firm. The catalogue is printed on art paper and contains numerous half-tone illustrations, which demonstrate the excellence of these lenses for all classes of subjects. A charge of which will be refunded on any purchase, is made for the list of those interested in high-class lenses can obtain a copy by sending this amount to Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn, London, E.C.

**MESSRS. SPIERS AND POND, LTD.,** have just issued a new and comprehensive catalogue of the photographic apparatus and accessories to be obtained at their stores, Queen Victoria Street, London. The list includes particulars of most of the well-known makes of cameras and hand cameras, lenses, shutters, enlargers, dark-room lamps, together with a variety of accessories and materials too numerous to mention. In short, it would be difficult for a would-be purchaser to visit this establishment to go away without having his requirements satisfied. This catalogue, which will well repay a perusal, may be obtained post free by any of our readers on application to Messrs. Spiers and Pond, Ltd., at the above address.

**DR. LOUIS MERCK**, of the firm of E. Merck, Darmstadt, has been granted the honorary degree of M.D. by the University of Giessen.

## Commercial & Legal Intelligence.

**PHOTOGRAPHER, WIFE, AND SUNDAY TRADING.**—At the Cleethorpes Court last week thirteen traders were summoned on charges of Sunday trading. Most of them pleaded guilty, and were fined 5s. 6d. costs.

A charge against John Hawkey, photographer, was contested by Wainwright. Inspector Sindall said the business was being carried on on Sunday, August 11. Mrs. Hawkey was in the studio, she said she was carrying on the business, and pointed out to the jury that the words "Mrs. Edna Hawkey" had been temporarily over "John Hawkey" in front of the shop. On the back of the photo, however, readable to people in trains and Poplar Road, the name John Hawkey was still there, and notices inside the studio the name John Hawkey. In answer to the officer, Mrs. Hawkey said she carried on the business entirely on her own behalf, but used using the plates and other materials which were in the shop, that she did not pay her husband for them. She assisted her husband at the studio during the week. In cross-examination, the officer said Mrs. Hawkey was giving receipts bearing the name John Hawkey. He did not see the defendant on the premises that Sergeant Johnson corroborated.

The defendant was called, and said he was not at the studio on Sunday, and had no interest in the business on Sundays. He charged the jury with the bare cost of the plates she used. He admitted that the charge was made for the plates. He transferred the case to his wife for the day to avoid the fine. The photographs were finished off in the week by him.

Wainwright submitted that the defendant could not be fined, as he was not following his ordinary occupation. He was never at the studio on this day, the 11th, and it was his wife's name that was on the studio door. It was true that the name John Hawkey was on the back of the premises, but this would be remedied at once. It was an oversight. (Laughter.) It was quite immaterial, he submitted, whether the wife had paid for the stock she used or not. If the Bench convicted, he said, it would be tantamount to saying that if a man went for a holiday, and another man went to business and carried on the business on Sundays in his own name, then on the holiday would be liable to be fined. He was perfectly satisfied with the Bench—it was an attempt to evade the law. They were going to make the transfer of the Sunday business quite complete. If the Bench wanted a deed they should have it. The Bench said they considered that it was simply an attempt to evade the law, and the defendant would have to pay 5s. and 6d. costs. "If he is not satisfied we shall be glad to state a case," said the Chairman.

**PASSING FRAUDS.**—William Stephen Mills, described as a photographer, was indicted at the Surrey Quarter Sessions at Kingston for obtaining money by false pretences from women in different parts of the county. Mr. Rowsell appeared to prosecute, and Mr. Guy Lushington defended, prisoner pleading not guilty.

Mr. Rowsell, in opening the case, said it was a most important case as the fraud had been practised only on poor people, several of them servant girls, and was of a most ingenious character. Prisoner was at Dorchester, but on June 15 he took lodgings at Addlestone, Surrey, and from that time until July 17 practised these frauds on a large number of poor people living in the neighbourhood. His object was to go to a house and ask the woman if she wanted her photograph taken, and if he could not get an order, then he offered to do a large photograph for her free, on condition that she would give him a frame for the enlargement. In many cases he succeeded in getting some small payment on account for the frame, but, having got the money, nothing more was heard about the frame or the enlargement. Prisoner represented that he was working for the "Fine Art Photographic Company, of Dorchester," whose address was given as Victoria Road, but when inquiries were made there it was found to be an ordinary dwelling-house, with absolutely nothing in it of "fine art" in it, not even a studio. There was a card on the front door, however, with the words, "Fine Art Company"

Witnesses having been called, Mr. Lushington urged, on behalf of the prisoner, that there was no false pretence, the failure to execute the orders being merely a breach of contract, which he intended to execute. The jury found the prisoner guilty, and he was sentenced to six months' imprisonment in the second division.

**EMBEZZLEMENT BY A CANVASSER.**—At Leicester Police Court last week Alfred Sylvestone, 24, photographer's agent, Goldsmith Street, Nottingham, was charged with embezzling 5s. received by him on account of his employers, the Atlas Fine Art Company, on July 30. Defendant was employed as collector and salesman to the company, and failed to account for 5s. received from Mrs. Cousins, going away and leaving a note at his lodgings to the effect that he had gone home. It was stated that the defalcations amounted to 17s. The accused was received in custody from the Nottingham police, and when charged said, "That was quite right." He now pleaded guilty, and said his pay was inadequate for the work he had to do. Fined 20s. or fourteen days.

**CHARGE AGAINST A CASHIER.**—At the Birmingham Police Court last week Wm. Henry Evans, chief cashier to Hurmans (Ltd.), photographers, Victoria Square, was charged with embezzling moneys of his employers. Evans resides at Stechford, and has recently come back from his holidays. While he was away his employers went through his books, and, it was alleged, found serious defalcations. Detective-Inspector Goldrick went to Messrs. Hurmans, and pointed out an item of £60 to Evans, who confessed to the defalcations. The officer stated that on the way to the station Evans confessed to him that he had been carrying on two businesses in the photography line, in Ashted Row and at Stechford, on his own account, and that it was these two concerns which were at the bottom of all the defalcations. Detective Goldrick also said that Evans had previously held a good position as an accountant in Birmingham. They were not yet ready to proceed with the case. The accountants were still at work upon the books, and he asked for an adjournment. The Magistrate adjourned the case for a week, liberating the prisoner on bail.

**SOUTHPORT BANKRUPTCY.**—On Monday, at Liverpool Bankruptcy Court, Mr. Britten, the Deputy Official Receiver, conducted the examination of James Shaw, a photographer, of Southport. The debtor was represented by Mr. John Sefton. The unsecured liabilities were stated to be £341 12s. 3d., and net assets £67 19s. 3d. In reply to Mr. Britten, the debtor stated that when he was employed as a labourer on the railway he occupied his spare time at photography. Fifteen years ago he started as a photographer, and the main cause of his failure was the destruction of a large quantity of photographs and picture postcards by high tides, storms, and rain. The place they were in on the Southport shore, together with about a dozen other places, was carried away by the high tides some time ago. The examination was ordered to be closed.

### NEW COMPANIES.

**MANSFIELD, LTD.**—Capital £2,000, in £1 shares. Objects: To acquire the business carried on at 12, Manningham Lane and 4, Snowden Street, Bradford; 245, Anlaby Road, Hull; Welford Place, Leicester; 16, Cloth Hall Street, Huddersfield; Baldwin Chambers, Baldwin Street; and 16, High Street, Bristol; 28, Bridge Street, Burnley; 46, King Cross Street, Halifax; and 39, Barrow Street, St. Helens, as Mansfield, and to carry on the business of photographers, dealers in photographic materials, etc. No initial public issue.

**LAWLEY AND DAVIS, LTD.**—£3,000 (£1). To acquire the business carried on by S. Davis, at Sherlock Street, Birmingham, as Lawley and Davis, and to carry on the business of photo-etchers, stationers, etc. No initial public issue. First directors (not less than two nor more than three): S. Davis and Mrs. E. Davis (both permanent). 100 shares. Remuneration (except managing director) as fixed by company. 206, Sherlock Street, Birmingham.

**THE NEWCASTLE PHOTO COMPANY (LTD.)** has been registered with a capital of £250 in £1 shares, to acquire the business of photographers and confectioners, carried on as the "Imperial Photo Company," at 3, Clayton Street, and 114, Westgate Road, Newcastle-on-Tyne. There will be no initial public issue.

## News and Notes.

**SCARBOROUGH AND DISTRICT PHOTOGRAPHIC SOCIETY.**—An exhibition of pictorial photography, the work of the members, will be opened in the School of Art, Scarborough, next Monday by the Mayor of Scarborough, and will include some of the best work of such well known exponents of the art of photography as the Brothers Wanless, Messrs. T. F. Brogden, A. H. Robinson, A. E. King, and F. Foster.

**RIGA PHOTOGRAPHIC SOCIETY.**—The Photo-Club of Riga (Russia) are holding an international photographic exhibition from April 19 to 30, 1908, both pictorial and technical work being admissible. Particulars as to medals, wall space, etc., may be obtained from Mr. O. K. Saldtner, Postfach, 223, Riga.

**THE ROYAL PHOTOGRAPHIC SOCIETY'S ANNUAL DINNER** will take place on October 30, at the Holborn Restaurant, the function having been fixed for a later date than in previous years in order to avoid the holiday season, and thus enable many to be present who might otherwise be out of town. The following gentlemen will act as stewards:—Mr. J. C. S. Mummery, A.R.I.B.A. (president); Sir Joseph Swan, D.Sc., M.A., F.R.S. (vice-president); Messrs. A. W. W. Bartlett; Leslie E. Clift; A. R. F. Evershed, M.R.C.S., L.R.C.P. (London); T. E. Freshwater, F.R.M.S.; John H. Gear; E. T. Holding; Fred. Hollyer; G. Lindsay Johnson, M.A., M.D., B.Sc.; Furley Lewis; Ernest Marriage; Arthur Marshall, A.R.I.B.A.; C. E. K. Mees, D.Sc., F.C.S.; F. J. Mortimer; C. Welborne Piper, A.R.I.B.A.; E. Sanger-Shepherd; J. Spiller, F.I.C., F.C.S.; and H. Snowden Ward. Applications for tickets may be made to any of the above, or to the secretary of the society, 66, Russell Square, London, W.C.

**PHOTOGRAPHING A LION FIGHT.**—An enterprising photographer of Copenhagen, being anxious to secure a realistic lion hunting scene for the cinematograph, proceeded to convert a small island in the vicinity into a tropical scene, into which he introduced horses, sheep, and sportsmen in typical lion hunting costume, the latest addition being two lions, purchased in Hamburg. The Minister of Justice, hearing of the scheme, gave orders that it should be prevented, but the photographer made a secret visit to the island, and, with the aid of his assistants, succeeded in carrying out his programme. The animals at first refused to stir, but eventually attacked one of the horses, and a desperate fight ensued. When sufficient film had been obtained the lions were shot, and the operators hurried from the spot; but the following day the photographer was arrested by the police, his films confiscated, and his licence withdrawn, the Minister of Justice also prohibiting the purchase of the films thus secured.

**THE PLATINOTYPE OUTING.**—The members of the Platinotype Company's works held their annual excursion on Wednesday, the 21st inst., Eastbourne being the place selected, and right royally were they entertained and provided for. There is a tradition in the Platinotype Company that what is worth doing at all is worth doing well, a principle which Mr. W. Willis carries out in its entirety when all concerned at the works become his guests for the day. Leaving Penge at an early hour Eastbourne was reached shortly after eight, the members driving to the Grand Hotel, where breakfast was partaken of. Here they were met by Mr. W. Willis and a small party who had motored down. A drive to Beachy Head and a ramble over the breezy downs made the morning seem all too short. On the return to the Grand Hotel over 100 sat down to an excellent dinner, Mr. E. J. Humphery and friends having by this time arrived. Dinner over, Mr. Humphery, in graceful terms, proposed the health of Mr. W. Willis. He (the speaker) always regarded those at the works as one large happy family, pulling together for one common end, with never a note of discord to break the harmony and good feeling which existed between themselves and their principal. Mr. Horsley Hinton said that for over twenty years he had been opening mysterious tins, evidently packed by deft fingers, and had also been associated with those responsible for the direction of the company's affairs. In future whenever he rotated a certain cutter lid it would bring back to his memory the fair and happy faces of those around him. He hoped to have the pleasure of meeting them all again. A cheery note of welcome next came from Mr. J. Willis, and finally Mr. W.

Willis rose to express his gratification at seeing all assembled again. He hoped they would enjoy themselves, and have many happy days together. To Mr. W. H. Smith (the manager of the works) and others his and their thanks were due for the arrangements made at very short notice. The company then dispersed in various directions, some attending a flower show at the Devonshire's residence, others seeking the attractions of including "The Beauty of Bath," whilst a few availed themselves of a steamboat trip to Hastings and back. The sea had the temporary appearance of a billiard table, but this did not prevent one or two young ladies from being temporarily overcome by the "beauty of briny," a state of things possibly accentuated by the recollection of a six-course dinner. Tea was served at six o'clock, and a comfortable journey home brought a "red-letter" day to close. Amongst those who wrote or wired expressing their regret at being unable to be present were Mr. G. E. Brown ("British Journal of Photography"), Mr. Snowden Ward ("Photographic Monthly"), Mr. F. J. Mortimer ("Photographic News"), Mr. P. R. Mortimer ("Photographic Dealer"), and Messrs. E. J. Wall and H. M. Wall (hon. secretary Croydon Camera Club).

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed in our correspondents.*

### PATENTS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—With reference to Otto Pfenninger's patent 25,907, 1906 ("B.J.," p. 581), permit me to call attention to the fact that the refraction compensator which he claims was patented by me in 1899—U.S. patent, No. 635,253, published October 1, 1900. In my Traill-Taylor memorial lecture for 1901, following a description of this compensator, occurs the following sentence:—"A known defect of the prism, which is the cause of the error, is remedied by the use of a compensator, which is now being instantaneously devised, used, and published by me."

Even my 1894 patent on "photochromoscope and photochromograph camera" shows the colour screens inclined to act as refractive compensators, although the reason therefore was not then stated. It is a fact that every inclined transparent mirror trichromatic light have ever used has been provided with one or another of the compensators which I devised.

Having once originated and published or patented such a device is not necessary to burden subsequent patent specifications with details, hence Pfenninger's ability to point out that such compensators are not shown in my subsequent patent drawings.—Very truly yours,

FREDERIC E.

Woodcliffe-on-Hudson, Weehawken, P.O., N.J.  
August 13, 1907.

### PATENT REGULATIONS.

To the Editors.

Gentlemen,—In reference to your article, "Patent Office Regulations," in this week's "Journal," I think that the authorities could put forth a system in the way of inventors if they so desired. To mention amongst others is the reduction of the time that elapses in the disposal of protective documents. The greatest obstacle, to my mind, to the interest of the inventor is the grave lingering poor applicant for his rights.

It is generally recognised that the authorities here are not so earnest in their care for the just claims of the true inventor in comparison with those of the United States. Under the present system it is the first introducer and first or second pirate, to be the results, who reap the benefits of the working brains of the true and deserving, but poor, inventor.—Yours very faithfully,

A LINGERING STRUGGLER

## Answers to Correspondents.

\* All matters intended for the text portion of THE JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPH REGISTERED:—

Lowthian, 144, Freeman Street, Grimsby. *Photograph of the s.s. "Marylebone."*

ROUBLED.—We explained the method fully in our issue of July 12, which please consult.

IXING.—I should feel much obliged if you would let me know the quantity of hypo required to properly fix one dozen whole-plate P.O.P., and whether alum could be used in the same bath.—J. T.

If we fixed all together we should like at least 10 oz. of solution, containing 1½ ozs. of hypo. This quantity would certainly fix a great many other prints, but we should not think it wise to exhaust it. Yes, you can make up an alum-hypo fixer (see "Almaazac," p. 964), first formula, but the plain solution is best for P.O.P.

Q.—Are the prints as toned by Mr. W. B. Ferguson as permanent as those toned in separate bath, if thoroughly fixed before toning in the combined bath? I have tried same, which works admirably, but do not want to sacrifice permanency.—H. WEST.

There is no reason why they should be less permanent.

There is no reason why they should be less permanent.

ANS FOR REFLEX.—I want to get a 10 x 8, or larger, lens for use on a 5 x 4 Argus reflex, to work at not less than f/8. My object is to get as large an image as possible in the case of natural history subjects, without the loss of intensity entailed by the telephoto lens. The maximum extension of camera is 13in., so that I cannot exceed that focal length. Will you kindly answer me the following questions? (1) What increase in size of image of a 7in. Holostigmat, Series I, as sold with the square Argus, may I look to get with a 10 x 8 of the same angle of view of 12in. focus? I take it I shall, roughly, get twice that of the 7in. on the focal length, and about twice on the extra size of plate covered—that is, about four times the image as given by the 7in. Holostigmat. Am I right? (2) Is there any objection to the use of a 10 x 8 on a 5 x 4? Does the light which does not act upon the plate tend to fog it? (3) Would it be possible to use anything bigger than 10 x 8 successfully? I am limited by my camera front, of course, which will only take 2in. mounts. (4) Given other things equal, would not a lens with angle 60 degrees give a larger image than one with angle of 90 degrees, assuming they are made to cover the same size plate? I want to be able to get a small object big enough to be enlarged without pushing it too far. You will know how hard it is to get, say, a bird even twenty feet away, of a decent size.—Non Sero.

(1) Yes, you are right. The image would be 12.7ths or 15.7ths the linear size. (2) None so long as the camera interior is properly blackened. (3) It depends on the back focus, which, we believe, in the "HoloStigmat" is somewhat shorter than the equivalent

focus. Therefore this is to your advantage, though the difference will not be much. You must remember you are not using the lens on distant objects. Altogether we doubt if you can use a longer focus, or quite so long as 12 inches for your particular work. Why not ask the makers? (4) Of course it would, but that is the same thing as saying a lens of longer focus would do so. You cannot speak of them as distinct qualities.

STAINED NEGATIVES.—How is it I get green stained negatives? I am using Ilford's pyro soda, stock solution (A), with Ilford plates. I have used this developer a number of years without any stained negatives. Before the plates are half developed the developer turns black. I have thrown one ounce of pyro away, also carbonate and sulphite, and made up a fresh lot, but still no better. Is it the nitric acid that causes it, or what is the cause and the remedy?—E. MOORE.

You have probably been supplied with a bad sample of sulphite. Try making a new lot of developer with a sample of guaranteed purity, such as Schering's, and we think you will find the trouble disappear.

MIDGET PHOTOGRAPHS.—(1) Where can I get a good stamp camera for copying, serrated paper, and masks for same? (2) A formula for a toning bath, which will work evenly? I am doing postcards in large quantities, and, although I keep them moving, they tone very uneven, much quicker at the edges, as enclosure.—W. E. M.

(1) Butcher and Sons, Camera House, St. Bride Street, E.C.; and J. Fallowfield, 146, Charing Cross Road, E.C. (2) The fault is probably not in the bath, but in toning too many at once. Why not try less? If this does not help you we can only suggest that you let us know the formula you use, and other details of your working, without knowing which we obviously cannot assist you.

GOVERNMENT OFFICIALS.—Is an excise officer allowed to carry on a photographic business in same town? Also are there any rules to prevent a post-office clerk from making profit from photography? This clerk styles himself an amateur, yet boasts of doing from 200 to 300 postcards of local events at 2d. each per week?—G. A. SMS.

It is out of our province to reply to your queries, but we believe the restriction as to other business varies in different Government departments and in the grades thereof.

PHOTOGRAPHIC RIGHTS.—I should be glad if you could say whether I am right in publishing the enclosed postcard of tomb, not having had permission to photograph it.—JAS. T. WILDER.

You are quite at liberty to publish.

PHOTOGRAPH ON A SILK HANDKERCHIEF.—Would you kindly give the process of printing a photograph on a silk handkerchief, if a reliable process is really known, as from inquiries through the trade it seems that no practicable information is known on this subject?—THOS. WILLIAMS.

Better obtain sensitised silk from the Platinotype Company,  
Bloomsbury Street, W.C.

DUTY ON CAMERAS.—I shall be obliged if you will inform me in your next issue if any duty is payable on cameras, lenses, etc., taken into Italy, Switzerland, and neighbouring countries. I purpose going to Naples, Rome, Venice, etc., next month, and I am given to understand that in some countries a very heavy ad valorem duty is charged.—VIATOR (Devon).

There is none on apparatus taken as personal luggage.

PROSPECTS OF ASSISTANTS ABROAD.—I am desirous of leaving this country for a while, and should like to ascertain what prospects there would be for me in Canada or United States as assistant. I am, and have been for two years, a commercial photographer, and am used to small postcard publishing businesses. My total experience is seven years, during which time I have touched almost every branch. Are wages and demand better in Canada, and what would be the best means of advertising for a situation, and in what paper, for the States? Should I have a better chance on the Continent, France, Germany, etc.? I am 24. I thank you in anticipation of a reply in "Journal" in due course.—W. H. P.

We very much expect that wherever you may go you will find the photographic labour market as well as, if not more, over-

stocked than it is in England. In Canada and in the States salaries may be a little higher than they are here, but the cost of living is also very much higher. Unless you are a really skilled photographer we do not think you will do any better abroad than you will here. In all the places you mention there are many very high-class photographers, and your qualifications do not appear to be of a very high order. Probably the best paper to advertise in in the States is the "Photographer," the offices of which are at 30 and 32, West 13th Street, New York.

**BRONZE POWDERS.**—We have just had delivered to us a batch of mounts, printed in error with bronze powder, which has got over the whole surface. We should be glad to know if this bronze powder has any effect on properly treated P.O.P. prints if left between the print and mount. Wiping off powder with cotton wool may not prove satisfactory. We have had experience with bronze powder printed mounts fading the prints in fine white spots, due, as we understand it, to the bronze powder. As the printers say it is not harmful we are asking your opinion on the matter.—**BRONZE POWDER.**

Certainly, we should not entertain using the mounts, as the metal particles are almost certain to spot the prints, unless the dry-mounting process is used.

**FOCUSsing GLASS AND DEFECTIVE VISION.**—I shall esteem it a great favour if you can enlighten me on the following in your "Answers to Correspondents" column, of which I am a constant reader. I have been using for six years the same focussing glass with success, but a short time ago, when I noticed on developing my plates, I found them all out of focus, although I brought everything up sharp on the screen with the glass, and, curious to note, when I focus without the aid of the glass, I get everything sharp; but it is difficult to me to do so on account of defective eyesight. If you can help me I shall be very thankful.—**R. E. SMITH.**

It is very obvious that the focussing glass is not adjusted to your present eyesight, which has evidently changed since you first had it. You will see the subject dealt with in "Ex Cathedra" this week.

**WORKING-UP.**—(1) Could you inform me as to what medium is used to prepare the surface of bromide enlargements for water-colouring by hand, also C.C. and Velox prints? (2) Should ordinary water-colours be used for the purpose? (3) Could you also tell me of whom I could obtain books on the subject, also working-up in black and white?—**ENQUIRER.**

(1) Apply ox-gall (artist's purified), using a tuft of cotton wool slightly moistened with this preparation. This will serve for the bromide and gaslight prints. For the collodion the best is:

Fluid extract of quillaia .....	1 drm.
Water .....	1 oz.
Alcohol .....	1 oz.

(2) Yes. (3) The best book is "Art of Retouching Negatives and Finishing and Colouring Photographs," by Johnson, 2s. (Marion and Co.)

**SPOTS ON PRINTS.**—Will you please tell me what is the matter with enclosed print and how to remedy it? The blue spots were originally blisters that appeared in second washing.—**R. M.**

As you tell us nothing of your working we can only conjecture that the spots are due to decomposed hypo in the prints; but what is the cause we cannot say.

**BROMIDE and Others.**—In our next.

**PHOTOGRAPHS OF MACHINERY.**—I have recently been called upon by a firm of engineers here to take some photographs of machinery at their place. When I sent the proofs they were returned, with the complaint that they were not good, and not at all like the photographs done for other firms. I went to see the people, and were shown some pictures which, I must confess, were a good deal better than mine—three of which I enclose herewith. You will see that there is not good detail in the shadows, and the bright parts are white and hard. In the other photos there is good detail everywhere, and the bright portions are not white

and hard as they are in mine. Can you please tell me how to get better pictures, as the firm there is a new one, and it is bringing business to me if I can improve the work?—**ENGINEER.**

It is usual, when machinery is to be photographed, to print over with a grey flattening colour. When that is done the bright portions become dull and non-reflective, while the other parts are, of course, lighter than they were before. This is probably what had been done in the case of the photographs you wish shown. On page 997 of the "Almanac" is a formula for a flattening paint, which can easily be cleaned off, after the photograph has been taken, with turpentine or petrol.

**G. J.**—We believe the sample of print is on one of the harder gaslight papers, of which one variety was made by the firm of Liesegang, who turned over their photographic business to the Bayer Company. Probably if you apply to them they can give you particulars of the paper.

**CANVASSERS' AGENTS.**—Our business being a club business, we employ canvassers on commission. Are we liable if the men offer goods at prices far below what is on our printed receipts, and also receiving more money than the receipt states they are to receive? Your favoured answer will greatly oblige, as we are having a lot of trouble over the matter.—**T. H. AND CO.**

As the canvassers act as your agents, any contract they make with customers is binding on you. If they agree to take portraits at a lower figure than quoted on your list you will have to take them at that price.

**A. WATTS.**—It is quite possible that the vibration will prejudice the use of the buildings for photography. We should advise you to allow your solicitors to look after the matter for you.

**D. D.**—Dyes are sold by the larger houses which will take to tints and prints. A useful preliminary treatment is with fluid extract of quillaia, 1 drachm; water, 1 oz.; alcohol, 1 oz.

**W. S.**—We have carefully considered the process described in your letter, and there are certainly some novelties in it. We think it workable, but we do not consider it patentable, as we do not see how it could be worked without, to an extent, infringing patents already in existence. Your letter has been destroyed as you wished.

**C. C. PRINTS.**—Can you kindly tell me the cause of the small black spots on the enclosed prints? Do you think they are due to iron particles in the water? The agents through whom I get the paper (C.C.) say they are, but I think they are in the paper, pieces of which I enclose herewith.—**C. YOUNG.**

The black spots are undoubtedly due to the paper. They can be clearly seen by looking through it before a strong gas flame. They are apparently in the emulsion and not in the paper itself. You would be perfectly justified in returning the paper to those from whom you got it.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Business and technical aspects of home portraiture are quoted in a recent address by Mr. C. Wesley Hearn. (P. 674.)

Qualifications which the photographer's receptionist should possess are the subject of some notes by a lady receptionist. (P. 675.)

Oil Process.—Although probably little will be seen of oiling at the exhibitions, there is much to be said for the use of process by the professional portraitist. (P. 671.)

Elaborate reflex camera for studio use has appeared on the market. (P. 671.)

Among the patents of the week are folding reflex cameras, one-colour processes, and a method of colouring photographs. (P. 671.)

Cheron has published some further details of apparatus which he employed in the prismatic dispersion process of colour photography. (P. 675.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

Lumière Process.—It is hoped that plates will be shortly made, in anticipation of which we publish some further instructions to the process. (P. 65.)

Martin Duncan, on the microscopic examination of an "Arto-ne" plate, reports the occurrence of carbon particles, but is able to identify the grains as those of potato starch. (P. 68.)

Abridged method of three-colour printing by transference of a film gelatine surface has been brought to a commercial stage by F. W. Donisthorpe. (P. 71.)

Last day for entries for the exhibition of the Society of Colour Photographers is to-day week, September 13. (P. 71.)

Instructions for the use of the "Sanzol" reducer for three-colour printing have appeared. (P. 71.)

We publish a further portion of the comprehensive paper on the mann process by Professor Cajal. (P. 69.)

## EX CATHEDRA.

### More About Blisters.

Since writing our article of August 30 on blisters we have seen in a contemporary the advice to "Beware of the bromide paper which sinketh not in the dish when it is wet, for the blisters anon will be many." Just before reading we noticed that a bromide print floating face up in a dish had developed blisters just at the points where the surface was exposed to the air. The paper in use had the property of floating to a marked degree and required a very abnormal soaking before it sank. At the time it looked as if contact with the air was helping the formation of blisters, hence we took the precaution of keeping the rest of the prints all face down. Later it occurred to us that the floating of the paper might be due to the same feature that we assumed to be the cause of the "osmotic blisters" described in our article. Small cavities in the paper filled with air would account very readily for the reluctance of the paper to sink. They would also account for the floating paper developing blisters at the points exposed, since the part at which the air sac exists would naturally float higher than the rest.

### An Unpaid Hand in the Dark-room.

It is remarkable how seldom in the dark-rooms of either the amateur or professional photographer one sees that most useful of accessories, a rocking-table. Either class, one would suppose, would find its assistance in regular work of such distinct value in reducing the proportion of failures or saving time that the little trouble and expense of installing it would be repaid. The larger proportion of development being done in dishes, and, in the case of professionals, with the pyro developer, there is always the necessity to put into practice the maxim of the text-book to rock the dish. And not in development alone, but in many other operations, a rocker is actually an extra assistant in the dark-room, and permits of a greatly increased output in a given time. Its value, of course, depends on the efficiency of the rocker, the best form of which for regular work is one of the pendulum variety, consisting of a platform mounted on a pair of knife edges and actuated by a weight of, say, 50 lb. at least. An occasional touch will keep the table steadily moving while the worker has time to attend to other things, and the mottling which is the result of neglecting to rock certain developers will never be the result of a few moments' inadvertence.

\* \* \*

### Cinematography of Bird Life.

An interested audience gathered at the Palace Theatre last Thursday to witness an exhibition of animated photographs of bird life which, from Monday evening last, have figured in the programme of the renowned place of entertainment

in Cambridge Circus. Mr. Oliver Pike, who, with Mr. Armytage Sanders, has committed to the sensitive film the domestic life of our best-known sea birds, himself explained a few of the obstacles which come in the way of the adventurous spirits who carry a cinematograph camera weighing sixty pounds down the face of such inaccessible places as the Bass Rock and plant it on the equivalent of the front doorstep of Mr. and Mrs. Puffin. From the series of films exhibited we can congratulate Mr. Pike on the first results of his enterprise in bringing before a London audience the life, and incidentally the humour, of the sea birds of our northern islands, and the management of the Palace Theatre equally deserves public approbation for this educative addition to a programme which is invariably the high-water mark of refined entertainment.

#### Evening Figure Studies with the Hand-Camera.

Among the occasions whereon the folding hand-camera, which is the tourist's usual companion, breaks down is when the light falls off at the end of the day. Although the provision of a small tripod will enable stationary subjects to be photographed as well as, if not better than, with the camera in the hand, anything in the way of figure studies unbeknown to the subjects themselves must be postponed until the next day. A lens of larger aperture, it is true, will admit sufficient light for a short enough exposure, but the difficulty of focussing with certainty then becomes a task which lies outside the capabilities of the average worker. The same lens, however, when a camera of the reflex type is used, will be found a most valuable addition to the outfit. In the country, whether in England or on the Continent, but particularly the latter, the hour preceding twilight is precisely the time when the best opportunities for figure studies occur. The sun has usually set before the people of a Bavarian or Tyrolean village return from the fields, and, in picturesque twos and threes and loaded with the tools or produce of their labour, betake themselves to their houses. In such circumstances a lens of aperture  $f/4$  and of focal length about 8 in. on a quarter-plate will permit of work which would be otherwise unobtainable. An exposure of 1-15th of a second is usually short enough to obtain figures free from movement, and is at the same time quite long enough to secure a full exposure to the plate. The doorway of the village Gasthaus zur Post affords a most favourable point of view, and we should not regard any tourist-photographer in search of negatives illustrating the life of the country

as well equipped for his work unless possessing the singular combination of large aperture lens, focal-shutter, and reflex camera.

\* \* \*

#### Sky Shades for Lenses.

It must not be forgotten that the use of large-aperture lenses, as suggested, there is a corresponding increased necessity for shielding the plate from the light which may be reflected upon it as a whole in addition to that which forms the image proper. Even with the blacking of the interior of a camera which can be done, there is bound to be a certain amount of reflected light, and the best course is to waylay the enemy at the opportunity—that is to say, before it has entered the camera at all. A lens-hood which prevents light falling on the lens at anything more than the angle of view is included in the picture on the plate is necessarily a better preventive of extraneous light than any means taken for absorption in the camera. The form of lens-hood recently made, designed by Captain Owen Wherry for telephoto work and made by Messrs. Beck, might be adopted in much hand-camera work with large apertures with great advantage. It could readily be made in a form for attachment to the front of a box camera and would have the virtues of certainty in use and ability to exclude light falling very nearly directly on the lens. In conjunction with the reflex camera, it would be a great help for the hand-camera worker to screen his lens effectively as when using the camera with all the accessories which can be exercised when using a stand.

#### Portraits of Notabilities.

A London daily paper, with which are associated several other daily newspapers, is just now issuing a request for a portrait to large numbers of persons who may be regarded as more or less in the public eye. A collection of portraits has of late become a necessary addition to the modern newspaper, which nowadays cannot wait until a photograph has been taken or procured of a person figuring in the events of the day, but must have it in the office in readiness for the photo-engraver. The fact may be taken as a hint to photographers to offer their services to editors of likely papers any portrait of a sitter who may shortly be, a celebrity, not when events have passed which bring the person into prominence, but in advance for the editor to file and use at his own convenience goes without saying that, as many people will themselves send to the press photographs on which no copyright

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### ONE-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the new edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

be charged, the photographer should not omit to state fully on the back of his print the fact of his ownership of the copyright and the amount of payment to be made him for the right of reproduction.

\* \* \*

**International Exhibition,**  
We see in the German papers that active steps are now being taken towards making the first official announcements of the International Exhibition of Photography, to be held in Dresden in 1909, before the photographic world. At the end of the present month 12,000 cards are to be sent out to members of the photographic profession and to those interested in the scientific and pictorial side of photography. The exhibition is expected to have the support of artistic, photographic, and scientific bodies in Germany, and though its organisation is in the hands of a German committee, there is the assurance that the aim of the promoters will be to make the exhibition representative of the status of photography in different countries.

\* \* \*

**Dr. F. D. Chattaway,** in a recent number of the "Chemical News," alludes to some experiments arising out of a research of his through which he has led to notice the very fine mirrors of metallic copper which are formed when solutions of copper oxide are reduced by certain of the aromatic hydrazines. At present, coherent film was obtained on the glass surfaces of vessels containing the mixed solutions, producing a mirror which exhibited the red lustre of burnished copper. The vessels possessed as perfect a reflecting surface as mirrors produced by deposition of silver. As Dr. Chattaway explains, the process may readily be applied in the production of objects of art, among them, we may surmise, photographic prints on a metallic base by the carbon process. The use of the copper process industrially would obviate the employment of the poisonous tin amalgam means of which the manufacture of mirrors is conducted.

\* \* \*

**Studio Camera**  
**Luxe.**  
Many of our professional readers will recollect the article of a couple of months ago, in which Mr. Gordon Chase described his practice of employing a reflex camera for a large proportion of his studio and "at home" portraiture. That such an aid to obtaining a bright and unstrained pose has been studied by others independently of Mr. Chase's suggestion is proved by the exhibition at a recent American convention of professional photographers of a new model of the Graflex camera, designed specially for use in studios. Several ideas are embodied in this camera, with the object of enabling the photographer to make photographs of children entirely without knowledge. A large dummy lens is fixed to the camera and is pointed towards a seated sitter, while the photographer is actually exposing on his child models on the other side of the studio. The focussing chamber of the camera is mounted on a turntable in such a way that the photographer looks horizontally into the camera while the latter occupies a high position and vertically downwards into it when a low view-point is selected. There are also other movements to simplify the working of the instrument, on which, so we gather from the description, an immense amount of care has been expended. Only the advantages of the reflex instrument in studio portraiture have proved convincing enough for a firm of the reputation of the Folmer and Schwing Co. to devote a camera for this branch of work alone.

## HOPES AND FEARS FOR THE OIL PROCESS.

THE publication last week of M. Puyo's full description of his method in the now worthily titled "*Procédé Rawlins à l'huile*" will no doubt still further stimulate the workers who have contemplated its progress since the announcement of its birth in the columns of our contemporary, "*The Amateur Photographer*." Since then the oil process has made copious "copy" for the British press and copious conversation in clubs and societies; but so far as actual achievement goes, the process appears to be the *métier* solely of a handful of enthusiastic gentlemen of France, who are working it for all it is worth, whilst Englishmen, for the present, either have not fallen victims to its fascination, or are, with characteristic stolidity, passing through the "looking on" stage which precludes all British movements. In view of the very English name that distinguishes the process, this fact is a little anomalous.

The truth is that a method which offers such scope for mental initiative as this does is much more appealing to the Gallic mind than to the Anglo-Saxon. Were it a matter of sport, ball-kicking or bird-killing, we should probably lead the van. But to work the oil process in the way that its advantages dictate requires a moral constitution not common among Englishmen. It will no doubt be agreed that if the method is to be of any worth at all there must be a light, venturesome, happy-go-lucky temperament, cheerfully callous of consequences, and with a dash of the illogical, or else there must be a mind and brain well primed with observations of natural phenomena, well used to subtleties and *nuances*, highly analytical, prompt to settle matters of choice, and quick to act; one able to make sacrifices without a pang of regret, and, above all, one cultured in that high school of taste whose wide portals invite everywhere, but are never found by many; whose fees are less than nothing, but beyond the income of the multitude. In short, the mind and brain of an artist "by birth and education."

It is to be feared that the time will have been too short at the opening of the autumn exhibitions for any national effort in oil to appear; but we may live in hopes. Mr. Rawlins himself, and others who have had much advice and many hints to offer in the photographic press for the last twelve months, may surprise us into national pride. Who can say?

Personally we think the country's reputation will be safer if the judges of exhibitions exercise a most rigorous selection by a high standard. It will be unfortunate if, by reason of the lectures, articles, club demonstrations, and so forth, a miraculous draft of fishy affairs are poured into our exhibitions, and thence, by the never-failing route, into our penny plain and twopence coloured papers. It is appalling to think what crimes may be committed in the name of oil-prints under the "encouragement" of society exhibitions. On the other hand, if judges will recognise that it is of more importance to show a very few of the very best than "encourage" every first attempt because, forsooth, it is a first, then the highness of the standard displayed will be a fine deterrent to the too-easily pleased oil-printer, and he will work the harder at seeing the goal so far ahead of him.

The more one reads and thinks about this process the more one is convinced that it must of necessity be as fire and edged-tools to nine out of ten who play with it. Already the methods of less facility in control have proved how little their workers have understood the things to be controlled. These well-meaning ones have been in the position of mariners with effective steering gear but lacking either chart or pilot; so that their manipulations have more often than not steered them into contrary currents and on to shoals and reefs.

M. Demachy has laid great stress upon the faultiness of tone-values in photography; but it would be interesting to know how many, beyond himself, could unerringly place their fingers upon faults of this kind in a good print from a well-exposed negative. Or, granting that they could do so within the narrow margin of such possibilities, is it a certainty that their emendations would not leap to faults at the other extreme?

M. Puyo, in his excellent little work upon this subject, sums up the advantages of the process into four heads: the controlling of local values, the placing of dark accents, the placing of light accents, and the sacrificing of parts. All this, to one who is on the look-out for such adventurous aids in the production of fine prints, would be of inestimable value. If in the past course of his work he had been trying to do these very things by more cumbersome and risky means, then he is the man that should jump at the oil process as something that should sweeten and prolong his existence upon earth. But to the man who has never been troubled about such matters, the man who is jealously careful in selecting his subject, whose care and pains come for the most part before the capping of his lens, and whose after-processes are carried through with the sure and certain hope that perfection will come of his long and studious practice: such a man will be but embarrassed, it may be, by the new view of things which M. Puyo's four headings open up. He would begin to think that he ought to go warily, on the look-out for certain camera faults taken upon trust. He may even be so far confused as to think that without control no photograph can hope to be artistic, and if he lacked any firmness in his own convictions he would probably end in a slough of despond and printer's ink. The last state of that man and his work would be worse than the first.

These remarks do not in the least argue anything against the position taken up by those who have proved themselves masters of the oil process; they merely state a fear of what will probably be the condition of those who are but the slaves of it. The use of it to the best advantage presupposes habits of mind and, to some extent, customary practices lying far outside the essentials of photography *per se*. Photographers who adopt it will not be advancing their craft; they will be paddling in the marginal surf of one of the arts. There is room for them, and a welcome for them, only, let them give heed to getting out of their depth. If the average Englishman has not been richly endowed with the graceful and tasteful temperament which distinguishes the Continental, he is at least fairly well equipped with the common sense that will save him from the ignominy which usually comes of playing a game he doesn't understand; and this probably accounts for the fact that England has so far not produced a crop of fine oil-process men: it is early days for them yet.

There is one avenue of work wherein it would seem that the oil process might become beneficial both to the public and to the "trade." We allude to professional portraiture. The very fact that duplication is difficult and is all but a repetition *ab initio*, exalts the results of the oil process to the footing of original works. This is exactly what many of the leading men have felt to be a desirable thing, as enhancing the monetary value of a portrait. The public are content that oil paintings and miniatures should be ordered singly; but they have got into the habit of thinking of photographic portraits in dozens.

To produce one print from a negative and then to smash the plate is as wicked and wasteful and horridly commercial as the destroying of a copperplate work before signs of wear. It is illogical, and an insult to the sitter. Suppose, however, that a professional man receives an order for a "brush-work photograph," or whatever other thing it may come to be called. He will invite the assist-

ance of an artist who understands portraiture, but is sufficiently affluent to be above the job. (No difficulty about that!) The man may be present at the exposure so that he may take note of the sitter and the effect. The printed film will then be handed to him to develop with his inks and brushes. He could do it in a day, and the photographer could charge his three guineas for it. If the customer wanted another, the professional man might urbanely make the great concession of knocking off the odd shillings. The work would be artistic in the real sense of the word, and if photographers retained their own artists there would be a distinct individuality about the work of each house which, under present circumstances, is hard to discover. Moreover, the better artist employed the greater the reputation and fee of the house. All this might revolutionise the portrait in its higher walks, would help many a deserving artist, and, most of all, would disseminate amongst the public examples of artistic work that would very certainly have educational value, with a reaction in favour of art with the big A.

And why stop there? The landscape cleverly tried might supplant the banal and trashy photogravure which still lives on by the dregs of a respectability it has positively no longer the smallest right to. Every well done is saleable, and these oil prints, if they are carried out with the cachet of the artist such as MM. Demachy and Puyo place upon them, might make a fortune for themselves, *pas-se-partout* mounted "*études*" of the sort that becoming indispensable ornaments of the drawing and smoking-rooms of *le beau monde*.

But this is looking too far into the future. For the present we must concern ourselves with the working results of the oil process in these its early stages. The prospects are bright enough, for it is happily so amenable a nature that it may be adopted by workers who desire a faithful print from a negative—a thing which the way, which both MM. Demachy and Puyo despise.

We have yet to be shown a "straight print" by the oil process, carried beyond the very experimental stage of mere demonstration. With such delicacy and strength and richness as the process can give, it should be possible to get fine pictures from those rare negatives whose local values are not in need of control, and in which the introduction of dark or light accents would be no advantage, and the suppression of passages a veritable artistic sacrifice. Must it be finally decreed that such negatives do not, never did, nor ever will exist? If it must, what a poor game our pictorial photographers have been playing! What exalted rubbish have we mutually worshipped! What insufferable airs and graces have they maintained!

The modest and earnest amateur who shrinks from the pretence of artistic perceptions he does not possess, who better go his honest way, doing his best, to his own and his friends' delight, improving his style and taste by contemplation of works of art and the prints of photographers better than himself. He had better avoid any attempted correction of photographic faults that he can detect for himself, by facile means that are not photographic. He had better, much better, pin his reputation to the "straight print," and leave to the artistic mixer the making of new pictures out of the ruins of old. So far as concerns the compensation for under or over exposure afforded by the oil process, he may be a glib by its adoption; but it is better discipline to suffer one's faults than to have them atoned for. The great danger is that he will be led to think that photographic results are in greater need of patching than they really are, and thus, by placing authority before conviction, may lead himself out of the frying-pan into the fire.

## RECEPTION-ROOM ROUTINE.

"When can you give me a sitting?"  
 "Tomorrow, madam, at twelve o'clock or at three o'clock,  
 or would suit you?"  
 "I think three o'clock would be most convenient.  
 I will be here at three to-morrow."

"Thank you, madam. Good-afternoon."  
 These words are as music to a receptionist's ear. They are the  
 after the exhibition of countless specimens of portraiture,  
 haustible patience, of persuasive sweetness, and of more  
 will-power. A receptionist's work resembles that of  
 ro of a penny novelette—it must have one's whole heart  
 hing, to make the tale end with the usual amount of

daily round is a very varied and exceedingly interesting  
 Contact with all sorts and conditions of men and women  
 one a zest and interest in life, and the lives of our  
 particularly those of political, social, and theatrical  
 that can rarely be obtained in any other calling; and  
 mind a receptionist's life should make her one of the  
 st of English women.

### A Receptionist's Accomplishments.

Amongst the chief qualities that go to make a successful  
 onist, I should include a good all-round knowledge of  
 unches of the business, including especially retouching,  
 g, and mounting, operating and miniature-painting,  
 as also to be able to write a good hand, to answer  
 in a business-like and tactful manner, to have a good  
 edge of book-keeping, and if she has some knowledge  
 versational French and German, her value is so much  
 her.

business ability must also enable her to detect instinc-  
 a chance of enlarging the business, and of following up  
 ail with the eye of a hawk and the determination of a  
 ound.

### Innate Tact.

One of the very important qualities for a receptionist  
 ous is tact, and it must be a tact that springs from the  
 kindness of heart, and the refinement of good breeding,  
 with the subtle intuition of a woman gives her a very  
 ching power. A tact that enables her to gain the  
 nce of a client before a word has been spoken—to feel  
 tively the price and style of portraiture to show them,  
 ithout any undue pressing to make that highest impres-  
 sion them that will induce them to arrange a sitting  
 or later. It only needs a sympathetic ear to the client's  
 a few choice specimens of the most suitable style for  
 ent, a few delicate hints of the highest results always  
 ed, and "Well, when can you give me a sitting?" is  
 suit.

One of the highest importance that the sitter should be  
 ed in a pleasant and inviting way, and sent up to the  
 feeling at peace with the world—pleased with them-  
 and confident that they are looking their best. This  
 rather an impossible task, but I am convinced that  
 ssible to surround oneself with such an atmosphere of  
 al and cheerful pleasantness that each client with whom  
 mes in contact is insensibly influenced by it. This mood  
 in turn influence the sitter's expression, and a most  
 ful sitting should result.

One must be largely exercised in obtaining payment from  
 . I have always found it best to ask for the full amount  
 time of sitting, and in cases of objection have carefully  
 ed out that I am merely obeying the rule of the firm.  
 g this, I always obtain a deposit, except in cases of  
 own clients.

### The Receptionist's Day.

My day is a very busy one. First there comes the finishing  
 touches to my reception-room, that leave it fresh and inviting-  
 looking for the day; and while on the subject I should like  
 to say that money spent on the decoration of the reception-  
 room is money that will return again and again. It is before  
 the studio in importance—it is the room in which the business  
 is made or marred—and the style of the room, its brightness  
 and general cosiness, should impress the clients in a marked  
 degree. There need not be an undue overcrowding of speci-  
 mens, but they should be of the best of their kind in their  
 spotlessness and in their selection of the studio's best effects.

Then comes the morning's post to be looked through—with  
 a keen eye to the bad orders and any complaints; accounts to  
 be made up, sitters to be booked up, and all the time the  
 telephone ringing and messengers and clients in and out.  
 Then, hurrying or altering proofs, taking orders, suggesting  
 alterations when needful, booking appointments, hurrying late  
 orders at the printer's, and arranging re-sittings when neces-  
 sary. Following this, the entering of the work of the day,  
 sending off proofs, looking up back clients who have not  
 ordered, and prospective clients who have not kept their  
 appointments. All this leaves little time to push for extra  
 work.

### Her Business Habits.

There are several very necessary items to keep this part of  
 the business in good working order. The proofs must look  
 inviting—neatly packed up, displayed in a small proof book  
 in the most inviting manner—and free from any small defect  
 in retouching that might prejudice the sitter.

Discrimination is needed in displaying suitable specimens to  
 meet the wishes of the client that will also display her charms to  
 the best advantage. At times it needs a great deal of per-  
 suasion to lead one of the portliest of the nobility from the  
 temptations of the full-length panel to the safer harbour of  
 the portrait bust. The higher-priced style of portraiture  
 should, of course, be shown first and the lower-priced kept out  
 of sight unless particularly asked for.

One somewhat neglected side is the attention shown to the  
 friends of clients accompanying them for a sitting. They  
 should be shown as much attention as any inquiring client,  
 and I have booked many appointments by "making hay" while  
 their friends are in the studio. No one should leave the  
 studio without being impressed by the excellence of the work  
 and the bright and pleasant atmosphere of the room. Every  
 sitter should at some time before or after a sitting have  
 brought to their notice the various enlargements, miniatures,  
 and pastels that surround every up-to-date reception-room.  
 They may not be intending purchasers at the time, but the  
 possibilities of such are, although unknown, very far-reaching.  
 With all respect to my sex, I have always found them the  
 strongest of advertising mediums, and a miniature of a well-  
 known leader of society in a prominent place in my reception-  
 room has brought me incidentally more orders than I shall  
 probably ever trace.

### The Studio Advertises Itself.

Attention to minutest detail is a very essential part of  
 my duties. I have known untold damage done to a firm  
 through one influential lady, whose disregarded directions on  
 some minor point of retouching has set a whole snowball of  
 damage rolling against their reputation for high-class work.

On the other hand, twelve well-finished photographs should,  
 on an average, bring in at least three more clients. Of the  
 absolute necessity for keeping all promises for proofs and  
 finished prints for a certain date, under all circumstances. I

need not dwell upon, this being the A B C of all successful business.

Lastly, and most important of all, a receptionist must bear in mind that "every day is a new day," and unless this is

realised in these strenuous times, and that her is bent on keeping up to date and ahead of her competence, her value can only be that of the second-rate order.

E. E. BARR

## HOME PORTRAITURE.

[The following address to the Convention of the Photographic Association of Vancouver and Connecticut deals so practically with the factors which enter into home portraiture as a branch of the professional photographer's business, that we have led to give the text of Mr. Hearn's advice in full. The paper is deserving of a careful perusal.—Eds. "B.J."]

HOME portraiture is all the more interesting and fascinating on account of the rather tough propositions that are always coming up during the process of making it. As an offset to the difficulty at times experienced, is the development of yourself as a resourceful worker, which is most valuable, and also the great variety of work that you produce, making a collection of pictures all the more interesting to the public, to whose taste we cater. It is, as we all know, very hard in the practice of our profession, under ordinary circumstances, to prevent our work from being all more or less of the same character. This fails to create the enthusiasm over our pictures by the possible purchaser who visits our studios, which is very necessary to encourage their sitting frequently, and otherwise extend our business. Whether we make much of a pursuit of the work or not as a business proposition in itself, it surely is advantageous for our indirect success that all of us at times go into these things, like home portraiture, as a trade-getter.

As a means of livelihood for the professional, considered independently of a regular studio with complete appointments, I should with much earnestness advise considerable caution. Our ranks are to-day provided with a number of amateur, semi-professional, and strictly professional home portraitists, among whom, in the professional class, Messrs. Histed, Pierce, Koshiba, and Henderson are among the more prominent. These latter gentlemen do work of a very high order, and their success here attracted a great deal of attention, and yet only one of the three mentioned, Mr. Henderson, is absolutely without studio appointments within his control.

### The Business Aspect of Home Portraiture.

At first glance it may appear that making a specialty of home portraits is a good money-making way of doing business, as the rent and other expenses of running a studio are done away with, and one could have his office at his residence; but the amount of the work done in the locality in this way is rather limited, besides requiring peculiar gifts in the ability to get a constant flow of customers.

When business is done with the magnitude or extent that Mr. Pierce accomplishes, north, south, east, and west, over large areas of the country, with the necessary extensive measures to accomplish its attainment, and the final execution and delivery of his work, with railroad and hotel expenses added, it eats into a great deal of money, and even the large price he receives is no more than the excellence of his work and the expenses attached to it entitle him to.

The rumours of high prices in connection with this work are, I think, the cause of so much attention being given it, whereas the pictorial effects so easily possible when making the work should attract all photographers to it.

The people who can afford to pay high prices for these pictures naturally expect to receive value for their money. It is evident, therefore, that he who would do this work should have a superior knowledge of pictorial effect, and ability to produce it. Added to this is the ability to accomplish all kinds of faking to overcome difficulties and assist in the carrying out of good ideas. This faking of the negative and of the print also during print-

ing is ever present with you. To succeed, it is of vital importance. The mere process of development is not a mechanical one, but requires slow, careful work, to obtain the very possible out of an exposure which, if it had been made in a studio, would have been discarded.

### The Wisdom of Reasonable Prices

Then again, the high prices themselves, often obtained, often an injury to the future of your business, if these prices impress people as unreasonable. It is also a mistake to think that even the very wealthy don't object mentally, if they do pay the bill. This fact has within a few months come to my attention in connection with an artist in a city where I reside. He informed me that he knew positively that his trade had been hurt in a certain section or because a patron who was well able to pay what she ordered paid him a large amount of money for a large order. She gave him, knowing full well what the bill was to be, told her friends what the price was she paid, without informing them particularly how much work she had. It spread rapidly, and her friends, less wealthy than this patron, went elsewhere for their work. He had expected great results from this of friends, but never had one of them.

In passing, it may be well for us not to pat ourselves on the back (nor hire someone else to do it if we can't reach it ourselves) when we receive a large remuneration for a limited number of pictures. It is well to bear in mind that the product is such that we wish and hope for other work to come from it, it would be far better in the end if we arrange prices, to some extent at least, so as to render possible the patronage of a number of her friends. Arrange these things, therefore, to bring some returns for this special fine you've made, and not let it go to waste, with only the person as the result of it.

The ability of the artist and the excellence of the work should receive proper returns, without giving the public an impression that the prices are extortionate.

### Practical Matters in Home Portrait Work

In the making of home portraits, the general illumination of a room in a house is far less than under our skylights if the surroundings be also dark, then there are no reflections and the results will likely be black and white; hence the use of a small reflector, which may be nothing but a towel or newspaper held up by an assistant or some member of the family, on the shaded side of the customer, and a little in the front. In doing this, watch that you do not reflect much light to spoil the shadow eye, or flatten out the shadow of the ear, making a noticeably dark and inky place from the nearly to the ear, and there very light.

Placing towels over the top of a two or three-flap screen be found in most every house, answers the purpose very nicely as at three or five or even more feet away it reflects sufficient light to illuminate without destroying the character of the sitter's expression. Blue tissue paper laid over the screen instead of white towels or cloths is also very good, and perhaps better.

Mr. Steadman, who makes marvellously fine home portraits with a kodak, has written a little booklet for the Kodak Company, costing about fifty cents, wherein, by drawings and text matter, he much simplifies the difficulties experienced by the beginner. I advise all those interested to obtain a copy of the book and practise in his own house with a 7 by 5 or 10 by 8 camera, with members of his own family, till he has become quite successful, before he attempts more serious cases. By this means he will also have practice in the development, which is a large part of the work.

Get a lens that works quickly, cuts well, and doesn't require a great distance, working reasonably near without distortion. A quick-acting, good lens is of great advantage.

### Hints as to Lighting.

A general rule for lighting the subject is to place her as far away from the light as the width of the window, and a little back from the window sash or pane-work. By this means the ill, direct light from the window, continued in a straight line as it travels, will pass practically in front of the face. The subject, however, will receive a mellow and powerful light, and by placing the chair a few inches this way or that, with suggestion to the subject of changing her position so she will face the window more, or vice-versa, very beautiful effects of lighting are easily obtained in the face (the more especially) and on the figure.

A narrow window and bright light will most likely produce strong contrasts, but this can be easily modified by changing position of the chair. Work to do all you can with the light itself, and make it a point to only use a reflector when absolutely necessary.

If in lighting you can get a little of the natural light on the other cheek, and still find room for your camera, the results are better. If you do this, and this light on the shadow cheek appears as very hard and sharp, then without changing relative position of chair with the window, place the chair a few inches

or a foot further away, and you'll find that the light in the cheek will still be there, but, not being so strongly marked, it will have softened or spread over the rest of that side, thus reducing the contrast, rendering almost unnecessary a reflector.

In bust portraits try and have the bulk of the light come from the upper part of the sash, screening the lower part of it with blue tissue, being careful in so doing that you don't prevent having a little snap of high-lights on the forehead and nose and a little less on the chin. Avoid extremes, however. A little doesn't mean so much that it merges all of the values of the face into one large white spot. Have just enough to prevent flatness, and so the head will be admired on account of the character or feeling that it has substances, and the face well delineated because its various facts are well indicated.

Fine pictures are made by experts where all sorts of combinations are made as to location, strength or weakness of the light, combined with the successful carrying out of all sorts of seemingly impossible effects; but you grow to this. Be satisfied in the first place to succeed in the preliminary stage, then your ability will be such as to successfully tackle and overcome more difficult things.

I have left for the last what is of vital importance, and that is the plate you use. By all means, for serious work of this kind, use ortho or iso-chromatic plates. All good non-chromatic plates will make house portraits, but it seems to me that with house portraiture a colour plate only should be the one generally used. Why? Because all the things in the room that take black, strong shadows in the face, etc., with an ordinary plate all take the same quality of black, or very nearly so, and the white objects are now unduly white amidst the gloom.

The isochromatic plate, used without a screen or filter, will show great differences between the darks in the negative, and will hold down too pronounced whites, or at least bring them nearer together as they appeared at the time. Don't try to make a reputation in home portraits with ordinary plates. Give it up and start straight.

CHARLES WESLEY HEARN.

## IMPROVEMENTS IN THE PRISMATIC DISPERSION PROCESS.

It seems fairly obvious that this particular process is attracting somewhat greater attention in France than here. The advantages are that it entirely does away with the use of filters other than the obviously necessary compensating or correction one that enables to obtain equal density throughout the spectrum. M. Cheron, whose previous work we have already recorded, suggests, in the present number of "La Photographie des Couleurs," further improvements in the apparatus.

One of the great difficulties in this process is obtaining the spectra equally sharp throughout the whole image. A microscopic examination of the negatives will show that as one proceeds further from the centre the spectral colours become confused, and are reduced to merely iridescent colours round the edges of the image.

The reason of this is very easy of explanation: the dispersion is not perfect, the colours not being well separated unless the light falls on the prism at the angle of minimum deviation. This particular condition is naturally very easy of attainment in an ordinary spectro-scope, but not so simple when one has to deal with the innumerable sources of light in the shape of the transparent parts of the screen. Another fact which is prejudicial, not only as regards the uniformity of the spectra in different parts of the image, but also to the sharpness of each spectrum, even in the centre, is that each beam of light passing through the transparent parts of the screen is conical, and therefore composed of rays which are not parallel, having their points in the transparent spaces of the screen and the surface of the lens as base, although to obtain perfect sharpness each beam should be composed of parallel rays, which should fall on the prism at the same angle, that of minimum deviation.

These two sources of aberration should be eliminated to obtain satisfactory results.

It is naturally impossible to obviate both at once, and to imagine an arrangement in which not only each beam should fall on the prism at a constant angle, but that each beam should only be composed of parallel rays. We must be content with eliminating one of the sources of aberration, and endeavour to correct the other as far as possible.

It is obvious, Fig. 1, that, although the extreme rays from the

Fig. 1.

edges of the screen *T* form when falling on the prism *Pr*, an angle of about 40 deg., the screen and the plate being placed each at double the focus of the second lens, the angle formed by the extreme rays of the same beam is relatively insignificant with a second lens working at full aperture *f*/6.

In fact, although each of the spectra formed by the beam falling on the prism at the angle of minimum deviation is really very sharp, in spite of the different inclination of the rays which has produced it, the difference in sharpness between the spectra of different parts is, as we have seen above, so considerable as to prevent one obtaining a satisfactory result.

It is chiefly the aberration resulting from the different beams falling on the prism at varying angles which we should endeavour to correct, so as to obtain on the plate spectra equally sharp in all parts of the image.

The arrangement which appears to be the most simple in appearance consists in suppressing the low-angled prism placed in front of or behind the second lens *O* and replacing with a prism *Pr* of greater angle placed close to the plate *Pl*, and placing a lens *L* of the size of the picture in front of this prism, so that its focus would exactly coincide with the diaphragm of the second lens, Fig. 2.

In fact, under these conditions, and to simplify the experiment, and taking into account the axes of the light beams, all the rays proceeding from the screen cross at the centre of the diaphragm of the second lens, and may in consequence be considered to issue from this point. Arising from the focus of the lens, on which they fall at an angle of about 40 deg., they are converted by it into parallel rays, and they meet the prism, interposed between the lens and the plate, at a constant angle for all rays of the image. This arrangement, so

Fig. 2.

simple in appearance, does not, however, give good results, for a reason which is very easy to understand: the lens, placed in front of the prism, not only gives refraction, but also dispersion. It acts, to some extent, like two prisms turned in opposite directions for the two sides of the image, and although this dispersion is added to that of the prism at the top where the angles of refraction are in the same direction, it totally destroys it towards the bottom, where the angle of refraction of the lens and that of the prism are in the reverse direction. It is obvious that one might use an achromatic lens, but in this size it would be difficult to make and its price high, but also, in all probability, its dispersion would still be evident, and would be augmented and decreased as described above.

A better solution is arrived at by modifying the shape of the prism and such a curvature to its faces, so that for all parts of the image the beam would fall on the refractive face at an angle which, if not absolute, would be more or less constant.

Supposing that, in lieu of using prisms with plane surfaces, we use one with curved surfaces, and that one of these faces, *LBM*, for example, is a section of a sphere having its centre at *O'*, that is in the centre of the diaphragm of the second lens, and for the radius *O'B*. All the axes of the beams will cross at *O'*, and may be considered as issuing from this point, it follows that they are all radii of the section of the sphere *LBM*, and, falling normally on it, will suffer neither refraction nor dispersion. But suppose that the exterior

Fig. 3.

face of this prism is also formed by the section of a sphere, which has its centre at *O''* instead of *O'*, the point *O''* being determined by the crossing of the line *BO'* by a straight line drawn from the point *A*, and making with *O'A* a given angle. If we now examine the dispersion suffered by the axes of the extreme rays *O'A* and *O'D* we shall find that it is exactly the same, inasmuch as these rays have not undergone any deviation in their passage through the first spherical surface of the prism, on which they fall normally, but that they suffer deviation and similar deviation in traversing the second spherical surface, which may be considered at the two points *A* and *D* as equivalent to two plane faces formed

by the tangents *III* and *JK*, and the two radii, *O'A* and *O'D* perpendicular to these two tangents form with the radii *O'A* and *O'D* angles, which are equal as having an equal distance from the points the radii *O'E* and *O'F* of the circle *O''*.

However, if the axes of the beams *O'A* and *O'D* suffer a small deviation, it is not absolutely the same for the axes of the beams for the centre of the image. In fact, for the central ray *O'C*, for example, for which the difference is greatest, it will be seen that the angle *O'CO'* is larger than the extreme angles by the distance *GO'*, which is, it is true, practically negligible. The results obtained with a prism of this sort are much better than those given by a prism with plane faces.

Unfortunately, the aberration, which is the result of the want

Fig. 4.

parallelism of the rays of each beam, is with this slightly greater than with the first arrangement. In fact, the curvature of the faces makes the extreme rays of the same beam cut this at a greater angle than if the surfaces were plane.

Finally, there is another solution, which is much simpler, and which gives excellent results. It consists in using a lens of very long focus to project on the plate the image formed by the screen. This projected image is comprised entirely in the region of sharp spectra formed by the rays falling on the prism with plane faces at the angle of minimum deviation, or at an angle very close to it.

One may use, for example, a lens of about 240 millimetres focus, screen *T*, and the plate *Pl* being placed at double the focus of the lens; there will then be an extension of 48 centimetres from the screen to the second lens, and an equal extension to the plate. If one adds a mean extension of 10 centimetres for a 6 x 6 cm. image, necessary to form the image on the screen *T* by a first lens, which can be done away with in any case, we shall obtain an apparatus absolutely ungainly proportions, 110 cm. long and 9 cm. deep. The rays are reflected twice by means of the mirrors *M*, or to reflection prisms in the body of the apparatus, its dimensions would be reduced, for stereoscopic pictures, 6 x 13 cm. to 38 x 20 x centimetres, Fig. 4.

As regards the second aberration, which so far has only been mentioned, the result of which is that each of the beams is not compo-

Fig. 5.

of parallel but oblique rays, this destroys, even in the better part of the spectra, the perfection of the same and the good division of the colours.

As we have already seen, this second aberration is more feeble than the first, for, although the angle formed by the extreme beams falling on the prism, in the absence of a long focus lens, is relatively considerable, yet the angle formed by the extreme rays of each beam is considerably less.

Still, it would be advantageous to eliminate this secondary aberration, and M. Lippmann has kindly suggested an arrangement which will obviously give every satisfaction. It consists in using a symmetrical doublet *O* to project upon the plate *Pl* the image formed by the first lens on the screen *T*, Fig. 5. It is well known that a symmetrical lens is composed of two lenses, or, rather, two combin-

tions, of equal foci, so that each has just double the focus of the whole.

Proceeding as we have already done—that is, placing the screen and the plate at double the focus of the second lens—it will happen that the screen is at the focus of the first combination, and the plate at the focus of the second combination. Under these conditions it is obvious that every conical beam of light proceeding from any point of the transparent spaces of the screen and passing through the first combination to the second, is transformed by this lens into a parallel beam, which, in passing through the second combination, is again converted into a beam of conical rays, which will converge on the plate into a point symmetrical with the point of the screen whence they emanated.

All the beams will then be conical in their paths in front of and behind the second lens, but in the interior of the lens each will be composed of parallel rays. All that remains to be done then is to place a prism with plane faces and low angle between the two combinations of the lens to obtain, at least where the beams fall on the prism at the angle of minimum deviation, spectra of absolute purity and with their colours perfectly separated.

This arrangement cannot evidently be combined with the two previous, which have been described, to correct the first aberration, unequal sharpness of the spectra in different parts of the picture, or they necessitate the use of a prism on the outside of the lens; but there ought to be every advantage in using it with the last arrangement—that is, with a long focus lens—so that the image could be entirely composed in the better region of the spectra. We could thus correct at once the two aberrations.

#### STAINS ON P.O.P. AFTER FIXING.

HAVE, during the past few weeks (writes Mr. E. C. Cripps in "Photographic Scraps"), had several small batches of prints, made in Ilford glossy P.O.P., spoiled by the appearance, generally during the final washing, of yellow or brownish yellow stains. The bath used was a combined toning and fixing solution, and although this is not the best method of toning, yet, having used it for many years and found it satisfactory, I was unwilling to believe that this was some obscure way the cause of the mischief. Thinking, however, that it might possibly have been the case, and knowing that inefficient fixing will cause trouble, and that a fresh combined toning and fixing bath will sometimes tone before the print is properly fixed, a separate fixing bath was used. Although the stains showed less often, they still occasionally manifested themselves. Their appearance was quite uncertain. One batch would be quite free, the next lot was hopeless! Needless to say, every precaution was adopted to prevent this staining. The prints were always kept in all solutions, and all dishes were used for nothing else but the same solutions. As far as I could judge, scrupulous cleanliness was always observed.

The cause of the stains has now been discovered in the shape of a duster hanging in the dark room, and used for wiping the fingers. While the prints were being washed plates were being developed and fixed in the dark room, and my assistant, wishing to take out washed prints, would wipe his fingers free from fixing solution on a duster badly contaminated with hypo, by this means making them rather worse than they were before.

His practice, of course, caused all the blemishes. It is a trite but very valuable saying that hypo, like fire, "is a good servant, but a bad master." A minute quantity in the wrong place will cause serious damage, in fact, most of the difficulties encountered during toning and washing are due to it. The obvious moral is that all operations should be conducted systematically, and that the photographer should do one thing at a time, and make haste slowly. The most important to thoroughly wash the hands between each operation, and scrupulous cleanliness in dishes, drying clips, and ferrotype plates and squeegees, should be always insisted on.

THE SILVER MEDAL given by the Morpeth Y.M.C.A. Camera Club for the best picture taken on the occasion of the visit of the Federated Photographic Societies of Northumberland and Durham to Morpeth on June 27, has been awarded to Mr. E. T. Robson, of the Dudley Camera Club, for his picture, entitled "A Sunlit Path," being a photograph taken in Bothal Woods. Mr. F. J. Mortimer very kindly acted as adjudicator.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between August 19 and August 24:—

**FOCUSING SCREEN.**—No. 18,737. Improved focussing screen arrangement for photographic cameras. James Lindsay Harvey, 100, Wellington Street, Glasgow.

**DAYLIGHT LOADING.**—No. 18,860. Improvements relating to methods for loading and unloading photographic plates and the like in broad daylight. Silvio Mela, 7, Southampton Buildings, London.

**CAMERAS.**—No. 18,934. Improvements in folding cameras. Cranley Lancelot Perry, 73, Cheapside, London, for Emil Wünsche, Aktiengesellschaft für Photographische Industrie, Germany.

**KINETOSCOPES.**—No. 18,945. Improvements in or connected with kinetoscopes and like apparatus. August Muger, 173, Fleet Street, London.

**LAMPS.**—No. 19,014. Improvements in lamps, more especially intended for photographic purposes. James Yate Johnson, 47, Lincoln's Inn Fields, London, for Jupiter Elektrophotographische, G.m.b.H. Germany.

**CAMERAS.**—No. 19,021. Improvements in folding cameras. Arthur Lewis Adams, 24, Charing Cross Road, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOURED PHOTOGRAPHS.**—No. 22,196. 1906. The invention consists in first leaving certain light spaces blank in the darkest portions of the picture when printing, and afterwards colouring these by any suitable process. The blank spaces may consist of fine lines, dashes, dots, or other blanks, and where lines or dashes are employed they may be of any desired pattern and inter-crossed or otherwise. The colours are then more effectively or satisfactorily applied by hand or otherwise to such lined portions or blanks of the print, because the shadows or dark portions of the print normally show through too heavily, whilst the shadows crossed with blank lines or spaces, according to this method or process, show up and display the colours very effectively.

The blank spaces may be formed on the sensitised surface in several ways. They may be obtained by ruling or be caused to appear upon ordinary sensitised paper, or alternatively, lines or rows of dots in some non-actinic or opaque colour or medium may be applied upon the surface of the negative so that the sensitised surface of the positive when printed shows the desired blank lines or spaces. Or, again, the sensitised surface of the positive may be ruled or printed before being darkened by the effect of actinic light, with opaque or non-actinic lines or marks of some medium, such as suitable pigment and water, which will first shield the parts of the sensitised surface lying thereunder from the action of light and will afterwards be washed off or leave such sensitised surface so that the lined or blank portions are produced.

If preferred, these blank lines may be obtained by interposing a line screen between the negative and the sensitised surface at the time of printing. The negative, the screen, and the sensitised surface are packed together in any suitable manner, so that the print is made as a contact print. The screen may be a lined screen, resembling that which is used in half-tone work mounted on a thin backing, or it may be a fabric of a textile nature or delicate lace or network, sufficiently open to allow the passage of light between the lines. This fabric will, by reason of the regular crossing of the threads, form a lined screen. Other forms of lined screen for this purpose may be produced by a ruled sheet of celluloid or tracing paper, suitably lined, dotted, or otherwise marked.

These blank lines or spaces may be hatched lines, and the lines may be crossed at right angles or otherwise. The lines, dashes, or spaces may be of any desired fineness of pitch, of one-half to one-fourth of a millimetre thickness and the same distance apart, affording satisfactory results in the case of whole-plate

photographs. For smaller photographs the lines might with advantage be finer and closer together. Barnard James Cooper, 31, York Place, Bedford Street, London, W.

**COLOUR PRINTS FROM ONE NEGATIVE.**—No. 716. 1907. The invention, which is an improvement upon the prior patents, Nos. 8,390 of 1896 and 15,185 of 1905, refers to a process of producing partial images "in closed tones," that is to say, without their elements being separated by interstices, from a negative taken under a three-colour filter, according to the known Smpolo-Brasseur process, described in the earlier of the two patents above mentioned, and so simplifies this process that but little practice or experience is necessary for carrying the same into effect, and it is especially applicable for taking small pictures.

According to the Smpolo-Brasseur process, either the negative obtained by means of the three-colour ruled colour filter or a diapositive printed from the negative, is so placed on the black and white ruled screen (composed of black and transparent colourless lines) used in this process for printing that the screen only leaves uncovered one of the three partial images.

This negative (or diapositive) thus covered is printed in such a manner that, during the exposure, the plate is moved through the distance of two colour lines of the colour filter by means of a fine threaded screw, and thus a partial image is obtained in "closed tones," that is to say, one in which the composite elements are not separated by interstices, instead of one formed by a series of lines and intermediate spaces. The other partial images are printed in a similar manner. Three plates are thus obtained, which are printed in the corresponding colours in order to produce the three monochromes by the superposition of which the final coloured image is obtained. By this process in the final coloured image, the colours do not contrast with each other as lines.

In order to simplify this printing process the present invention consists essentially in substituting for the displacement of the plate during exposure a partial rotation of the negative (diapositive) of the black-white screen and of the plate as a whole, first to one side, and then to the other side, around an axis parallel to the lines of the screen, so that the rays of light impinge at a corresponding angle; those parts of the plate covered by the black lines of the screen are also exposed, thereby "closing up" the elements of the partial image.

The process is carried out as follows:—

The negative produced under a three-colour ruled screen is fixed in a suitable printing frame, and the black-white screen made of thin glass or mica, and suitably framed, is then so placed upon it that it leaves uncovered only one of the three partial images. The sensitive plate is then laid on the screen and pressed closely against it by spring action (as in the ordinary printing frame).

The printing frame is so arranged on pivots that it can be turned around an axis running parallel to the lines of the screen. It is preferably arranged in the lower part of a deep box, the printing being effected by means of intense light, preferably sunlight. Whilst printing, the frame is turned slightly, first to one side and then to the other side. All the three partial images are printed in a similar manner. Charles Louis Adrien Brasseur, 121, Potsdamerstrasse, Berlin.

**FOLDING REFLEX CAMERAS.**—No. 17,359. 1906. The invention consists essentially in constructing a focussing device comprising a focussing screen and a mirror for inspection thereof, mounted so as to be instantly brought into their respective positions (in combination with a film pack carrier, plate carrier, or film roll holder), and capable of being instantly removed again out of the path of the rays of light, as the film or plate carrier is moved into position for an exposure.

In the arrangement shown in Figs. 1 to 3, the mirror is hinged to the adapter A by one edge in such a manner that when the focussing screen B is vertical in the focal plane the mirror C will fall to an angle behind it that will enable the operator to see the image thrown upon the focussing screen by the lens. And when the focussing screen B is folded forward out of the optical plane the mirror C can also fold or fall forward out of the optical plane. Behind the mirror C a frame or carrier D to carry films or plates is hinged. The carrier D is so hinged or pivoted that it can be swung round to bring the sensitive surface into the

optical plane in the place of the focussing screen B, while focussing screen B and mirror C swing forward out of the optical plane and clear of, or out of the path of, the rays from the lens. A link *c* is pivoted to the focussing screen with a slot

Fig. 1.

notch to engage a pin *b*<sup>4</sup> on the mirror C to hold them in their respective positions when focussing, and by which the focussing screen B can be manipulated to move it from one position to another. The mirror C may be held in contact with the carrier D by a catch, and may be caused to fold out of the optical

Fig. 2.

by a spring placed upon its pivot. An auxiliary mirror C<sup>1</sup> may be hinged to the adapter frame A if desired. (See Fig. 1.)

The focussing screen B, the mirror C, and the film or plate holder D may be geared to operate together by pinions *d*, their respective pivots, and rods *d*<sup>2</sup> provided with racks *e* and

Fig. 3.

ally pivoted at one end to a disc F, by means of which, as the holder D is moved, the focussing screen B and the mirror C are raised or lowered to their respective positions. (See Fig. 1.) The holder D may carry a roller blind shutter E of any ordinary construction (see Fig. 2), or the shutter may be applied to

lens in any ordinary way. To focus a picture the film carrier D is drawn back to its limit, which will be an angle of about 45 degrees with the foundation frame, at the same time bringing the mirror C back to the same angle. The mirror therefore serves as a protection or opaque cover to the sensitive films (when a focal plane shutter is used the films have the further protection of the shutter blind). By the same movement the focussing screen B is also brought exactly into the focal plane. The several parts are retained in their respective positions by suitable catches or detents. To expose the sensitive plate the carrier or holder D is moved back to the focal or optical plane, the focussing screen B and the mirror C moving forward into a position outside the focal rays. The shutter is then operated in the usual way, or it may be so arranged that the closing of the carrier or holder D into position for exposure will simultaneously release the shutter.

The specification also includes a description and drawings of a similar principle, involving the use of a flexible mirror and focussing screen. John Edward Thornton, Altrincham, Cheshire. SELF-CAPPING BLIND SHUTTERS, No. 17,358, 1906.—The first claim is for a roller-blind shutter constructed with two blinds geared together to move as one, the rollers of the blinds geared together to move in unison and reciprocating mechanism by which the two blinds are moved together in one direction for one exposure, and in the opposite direction for the next exposure, with or without means for adjusting the exposure aperture, such shutter being applicable either as a focal-plane shutter, a hood shutter, or a between-lens shutter.

Instead of using a pair of rollers of the kind generally employed for blind shutters (one being a plain roller and the other a tube having a spiral spring inside which drives the roller), two plain rollers are used, and the two ends of the blind attached as usual. These two rollers are mounted to turn in suitable bearings at opposite ends of the case or framework, and are geared together in such a manner that they always turn together, the rollers and blind moving in unison as one piece. They are best connected with the endless chain and sprocket wheels.

In use, the blind is rapidly moved in one direction to make an instantaneous exposure, and in the opposite direction to make the next exposure; whilst for prolonged exposures, generally called "time" exposures, its movement is arrested at the "full open" position for the desired period of time.

Motion is given to the blind by connecting up a strong spiral spring in such a way that it will operate some portion of the movable parts, such as one of the rollers, or the chain, preferably the latter. On one side of the case or framework is mounted a disc capable of rotating freely upon a fixed stud attached to the case, or else attached to a shaft that turns in suitable bearings. This disc is connected to the working part that operates or connects the two rollers, by a connecting rod, or other suitable mechanism for converting rotating into reciprocating motion. This disc makes half a revolution (or less, for instance one third) for each exposure, and the relative range of movement of the roller sprockets and the driving disc are such that the small angular movement of the driving disc carries the blind far enough to complete its movement from start to finish.

Adjacent to this main driving disc is mounted another disc capable of turning loosely about the same shaft or centre. The edge of this disc is grooved, like a pulley, with a deep half-round groove. Around the disc is placed a long pulling spiral spring of steel wire, secured at one end to the edge of the disc by a pin, and at the other end to a movable piece or key on the case, whereby the tension of the spring may be increased or diminished. In use this spring lies in the groove, and passes round the disc when the latter is turned by the operator, by means of a stud, crank, or key attached thereto.

The driving disc and spring disc are connected together by means of a ratchet and pawl, in such a manner that the spring disc can be freely turned in a backward direction to wind the spring thereon and place it at full tension ready for working the blind, but the blind is held from moving by a detent, and not until this is released by the operator does the spring disc become free to turn in the forward direction. The moment this detent is removed, however, the tensioned spring immediately turns the released spring disc, and the pawl carries the main driving disc round, thus operating the shutter blind instantaneously; upon

re-winding the spring the movement can be repeated as often as desired. The motion of the driving disc is always in one direction, and the reciprocating piece connected thereto gives the blind a to and fro movement, to enable an exposure to be made at each half of the movement.

A single blind shutter such as described may be made in various sizes and forms of case to suit the several positions already named, and in each form it dispenses with the necessity for any lens cap or auxiliary self-capping safety blind to the shutter in order to protect the plate during setting.

For a focal-plane shutter, however, it may not only be constructed in the simple form described, but may be provided with means for varying the height of exposure aperture in the blind, commonly understood as an "adjustable slit." For this a duplicate blind is used of exactly the same size and construction as the one first described. This is placed in close proximity to the other, the respective pairs of rollers being one in front of the other, or one above the other. The two sets of rotating parts are then geared together, so that all move in unison. This gearing and means of adjustment may be varied to suit circumstances. Suppose, for instance, the top roller of each blind carries a pinion that gears into the similar pinion of the other; both blinds would move together, and the height of slit be a fixture. But if one of these pinions was loose, that is to say rotatable upon its blind roller shaft, upon rotating the shaft whilst the pinion was loose, and then clamping the pinion and shaft securely together, it will be obvious the height of the slit would be varied to any desired degree. This is the simple principle of the arrangement, the two blinds are locked and travel as one for exposure—first in one direction for one exposure, and then in the opposite direction for the next exposure—and are unlocked to alter the slit, then clamped again for exposure. The means for carrying this out are modified to suit the maker's requirements.—J. E. Thornton, Altrincham, Cheshire.

SIGHTING AND PHOTOGRAPHING OBJECTS.—No. 10,701. 1906. The invention consists of apparatus adapted for sighting surrounding objects otherwise concealed from view, as, for example, the sighting from a submarine boat, when below the surface, of objects above the surface between it and the horizon, or it may also be applied in photographic surveying of objects comprised in the surrounding landscape between the apparatus and the horizon.

The invention has for its principal object to provide means whereby it shall be practicable to obtain at one time an angular field of vision having a range of 360 degrees.

The apparatus comprises an annular transparent and stationary prism in combination with one or more lenses, whereby the prism is adapted to simultaneously receive light rays proceeding from objects that may be located at widely different points of the compass and to reflect such rays, which, after emergence from the prism, are taken up by one or more lenses and, for observation or other purposes, projected on to a suitable surface or screen, or in some cases the produced image may be viewed direct as through a lens that constitutes an eye-piece or ocular. If it be desired to alter the direction of the rays that emerge from the annular prism, one or more mirrors or auxiliary prisms may be provided in suitable relation to other optical portions of the apparatus. Horace Frederick Denston, 178, Clapham Road, London, S.W.

## New Trade Names.

IMPERIAL.—No. 294,497. Photographic sensitised paper. The Imperial Dry Plate Company, Ltd., Ashford Road, Cricklewood, London, N.W., manufacturers of photographic materials. July 11, 1907.

THE COLOUR PHOTOGRAPHY EXHIBITION.—The annual exhibition of the Society of Colour Photographers will be held at the house of the BRITISH JOURNAL from September 30 to October 26. Full particulars were given in our "Colour Supplement" for July 5, page 54. Entry forms, which may be obtained from the hon. secretary, Mr. H. J. Comley, Surrey House, Stroud, Glos., must be sent to that gentleman, duly filled up, by September 10, and exhibits must reach the "B.J." Offices by September 13. Entry forms and full particulars may be obtained from Mr. Comley at the above address.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Value of Silver Residues from the Fixing Bath.

If we take as a rough average (writes Mr. H. Lloyd Hind, in "The Photogram" for September), 0.06 gramme (= .0025 ounce), as the amount of silver dissolved from one half-plate in fixing, we arrive at the fact that one ounce of silver is obtainable from the residues left after fixing 400 half-plates, which residues are consequently worth about 2s. To most amateurs, who do not expose half that number of plates in a year, the amount saved is inconsiderable, and would not repay the trouble of collection. But to the professional the waste of exhausted fixing solution may represent a serious leakage.

### Reflex Cameras for Animal Subjects.

One objection made to the reflex camera for animal studies (writes Mr. W. T. F. Wastell, in "Photography,") is that the focal plane shutter makes a great noise and is likely to frighten one's subjects away. Certainly I have never known a focal plane shutter that even approximately merited the term "silent." On the other hand, I have never found any disadvantage from the noise. The other day I had sidled up as close as possible to a parrot on an outdoor perch, and was standing at still closer quarters to another. When the shutter went off the parrot at my elbow fell off its perch with fright; but I got the other one all right. The fact is that even if the subject one is taking is startled by the noise, there is no harm done: the exposure is made. I have even known the clicking sound made by winding up the shutter to be useful in attracting attention.

### Autumn Mists.

In many scenes on autumn mornings (writes Mr. A. W. Cooper in "Focus") contrasts are at once sharp and soft, sharp in that the heaviest shadow can be placed against the lightest misty background, and soft because the outline grows more and more suggestive as the planes recede. To secure such effects, backed plates are an absolute necessity, the negative requiring to be kept soft and silky without excessive contrasts, and such as would delight the enlarger's heart. This type of negative can be got by giving a full exposure, any tendency to under-exposure resulting in the foreground being rendered too darkly, and effectually spoiling the feeling of lightness and buoyancy so prevalent in pictures of this type. Care should also be taken that the printing process chosen is in keeping, a rough, heavy paper or a warm tone being equally out of place. Smooth platinum or bromide papers seem most suitable, and are preferably mounted so as to carry out a scheme of harmonious greys, cool, delicate colours being more in keeping than heavy contrasty ones.

## New Materials.

"Adhero" Matt Tints. Made by the Adhesive Dry-Mounting Company, 27-28, Fetter Lane, London, E.C.

In introducing this series of mounting papers, the Adhesive Dry Mounting Company are catering specially for those adopting multiple mounting in their exhibition or commercial work, in both of which spheres of photography the exquisite process which bears the name of their firm has proved its value. And it is true to say that in both the importance—in fact, the necessity—of the perfect adherence and flatness which are obtained by dry-mounting are becoming widely recognised. The series of mounting papers, specimens of which have been submitted to us, represents a further advance in the convenience of the dry-mounting method, inasmuch as they are coated with the resinous adhesive, and do not require the separate use of the "tissue" which in the ordinary way is interposed to attach the prints to its mount. A saving of time, the incorporation of the adhesive with the tint paper is also advisable when, as is often the case, a considerable number of mounting papers are employed in the presentment of one single photograph. When that is done, the extra thickness of the tissues may detract

from the neatness of the mounting, and for this reason the self-adhesive papers will be welcomed.

The choice of colours in which they are obtainable is ample for the most varied forms of photographic print, since it includes two fine matt blacks, several good greys, and a selection of quiet browns and greens. There is not a single paper which can be called asstative—each in colour and texture has the quality of reserve in accordance with a style of mounting which from its nature must be employed with niceness and neatness in order to obtain its full effect. The names of the papers at present available are as follows:—Ash grey, Maltese grey, Scotch grey, slate, steel black, black, carbonette (a buff), light Napoli, dark Napoli, brown, sage, light blue, ivy green, and dark blue. In each of these colours the paper is sold in 24 by 20 sheets at 8s. per quire, or in 1s. packets containing a number of pieces of any desired size.

We can cordially recommend these accessories to dry-mounting as certain to still further recommend that valuable process.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, SEPTEMBER 7.

Leeds Camera Club. Excursion to Bolton Abbey and Woods.  
North London Photographic Society. Outing to Edgware.  
North Middlesex Photographic Society. "Record" Outing to Bury Street.  
Hackney Photographic Society. Outing to Bostal Heath.  
Rugby Photographic Society. Outing to Warwick.  
United Stereoscopic Society. Outing to Hyde Park.  
Bowes Park and District Photographic Society. Outing to Great Bookham.  
Bristol Photographic Club. Outing to Frampton Cotterell.  
South Suburban Photographic Society. Outing to Leigh and Benfleet.  
Edmonton and District Photographic Society. Outing to Waterlow Park.

#### MONDAY, SEPTEMBER 9.

Bradford Photographic Society. "Discussion on Winter Syllabus."  
Southampton Camera Club. Discussion, "The Aim and Scope of Photography."

#### TUESDAY, SEPTEMBER 10.

Hackney Photographic Society. "Photography by Night." W. H. Witts and J. Linley.

#### WEDNESDAY, SEPTEMBER 11.

Edmonton and District Photographic Society. "Velox Papers." Competition, August 5 Prints.  
Worthing Camera Club. Outing to Burpham, via Arundel.  
Leeds Camera Club. Evening Exhibition of Members' Work.  
North Middlesex Photographic Society. "Copying." S. H. Bentley.

#### THURSDAY, SEPTEMBER 12.

London and Provincial Photographic Association. "Ortho Plates for Landscape Work." W. T. Wilkinson.  
Handsworth Photographic Society. "Bromide Toning." J. A. Swift.  
South Suburban Photographic Society. Outing to St. Paul's Cray.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday last, before the members of this society, Dr. A. R. F. Evershed gave his interesting and instructive lecture, entitled "A Little Light on Lenses." In the choice of a lens the lecturer advised the sacrifice of a little quality in other apparatus, if necessary, in order to get the best lens possible, as nearly everything in photography depended on this, and he would give his preference to a second-hand R.R. lens by a maker of high repute above a cheap anastigmat. The lecturer then described the various types of lenses now in use, their faults and virtues, and gave instructions how photographers might find out themselves such things as focal length, aperture, hyperfocal distance for fixed focus cameras, etc. The method of testing a lens for astigmatism, actinism, spherical aberration, etc., was shown, and the action of supplementary lenses also described. These are often, but wrongly, called magnifiers, but they do not magnify the image, but only alter the focus of the lens to which they are attached. Several diagrams explanatory of the action of a lens were shown on the screen, also photographs of a test chart taken with various types of lenses, single and compound, showing the aberrations produced by each, together with those taken with first-class modern anastigmats, the difference being very apparent. Some portraits and landscapes were also shown, produced by the Puligny lens and the adjustable landscape lens, both of which have considerable outstanding spherical

ration, but have their advantage in giving softness and roundness of image, this being well exemplified in the portrait work shown. The adjustable landscape lens is especially useful for its work, as the lens can be adjusted to anything from about 6 in. to 28 in. or so, but, of course, at the long focus adjustment the lens is rather slow, as diaphragm aperture remains the same. These lenses being unexpected have the additional merit of being cheap. Mr. G. F. Evershed, in proposing a vote of thanks to Dr. Evershed, remarked that this lecture might well have been entitled a "lot of light on lenses" for the thoroughness with which it had been got up, and that it had cost the lecturer a great deal in time and labour. A final vote of thanks to Dr. Evershed was then carried.

**BERKEEN PHOTO-ART CLUB.**—The annual general meeting of the Berkeem Photo-Art Club was held at the club rooms, 62, Fonthill Road, last night, Mr. G. L. Smith, president, in the chair. The Treasurer's report showed the funds of the club to be in an exceptionally satisfactory state. An interesting and instructive programme was arranged for the coming winter. The following were appointed office-bearers for the ensuing year:—President, Mr. G. L. Smith; vice-presidents, Mr. James T. Jeffrey and Mr. W. R. Gregor, M.A.; secretary, Mr. John Rae; assistant secretary, Mr. A. Kennedy; treasurer, Miss M. R. Smith; lanternist, Mr. J. D. Stephen; assistant lanternist, Mr. W. Cook; committee, Messrs. H. Smith, A. Dalgity, M. Robb, C. Stephen, and Messrs. J. McCulloch, C. Smith, and H. Webster.

## CATALOGUES AND TRADE NOTICES.

**SECONDHAND APPARATUS.**—An after-season sale of secondhand and soiled apparatus is now being held at the various houses of City Sales and Exchange, and the manager of the branch at Aldersgate Street has forwarded us a copy of the list of "bargains" which is obtainable at that establishment. These include a large variety of cameras (hand, field, and studio), lenses, and enlargers by a number of well-known makers, all of which are being offered at prices far below their original cost. The list will be sent post free on application to the above firm at 81, Aldersgate Street, London, E.C., and any apparatus will be forwarded to would-be purchasers on approval against deposit. The sale is now in progress, and early application for a copy of the list is therefore to be advised.

## News and Notes.

**MATTHEW'S (BOOTLE) CAMERA CLUB.**—A change has been made in the secretaryship of the above club, and communications should be addressed to Mr. J. B. Potter, 19, Somerset Road, Bootle.

**SUNDAY TRADING.**—A curious defence was set up by a photographer from Saginaw, U.S.A. When charged the other day with Sunday trading he stated that he was an Adventist, and observed Sunday holiday!!

**WOMEN PAPER.**—Mr. H. Johnstone, Castle Douglas, N.B., writes: "With reference to question asked in your last issue, 'Lady' should try a carbonate of soda bath for purple tones on minimised paper."

**THE BIRMINGHAM PHOTOGRAPHIC COMPANY, LTD.,** announce that prize-winners in their recent postcard competition were: First (one guinea), W. Cheetham, Oldham; second (one guinea), R. H. Fry, Manchester; third (half a guinea), W. M'Lean, Belfast.

**GLASGOW PHOTOGRAPHIC ASSOCIATION.**—The annual exhibition will be held from December 31, 1907, to January 4, 1908, inclusive. Entries close December 18, 1907. Further particulars and entry forms may be obtained from the Hon. Sec., Mr. R. Telfer, 138, Glasgow Road, Glasgow, N.B.

**THE LATE PROFESSOR CZAPSKI.**—Dr. Moritz von Rohr, of the technical staff of Carl Zeiss, contributes to the "Zeitschrift für Instrumentenkunde" (Heft 8), a review of the work of the late Professor Czapski in optics. Dr. Czapski's earlier work, in association with Professor Abbe, had an important influence on the theory of

optical instruments, not only from his original research, but as a consequence of the editorial labours with which, especially towards the end of his life, he occupied himself. The science of optics lost one of her most brilliant students in the early death of Siegfried Czapski.

**AN OLD FRIEND.**—Much has been said about the aid which photography gives to the police in the identification of criminals. We are told that from Rome the other day six photographs, in different poses, of the same criminal who had escaped from prison were sent to all the different communes. From one official came the following letter:—"Five of the criminals of whom you sent the photographs have been arrested; we are on the track of the other." The last time this story went the rounds the scene was laid at Moscow.

**INTENSIFYING BROMIDES.**—The circular of the Manchester Amateur Photographic Society recommends the following process:—

- (1) Bleach the print in:
 

Copper sulphate .....	200 grs.
Potassium bromide .....	200 grs.
Water .....	20 ozs.

(This bleaching solution will also serve for sulphide toning.)

- (2) Wash well for five minutes and then—

(A) If the image is flat from over-exposure develop with rodinal 50 drops, water 3 ounces.

(B) If the image is flat from under development, develop with silver nitrate 10 per cent. 50 drops, water 3 ozs.

Finally wash well and dry.

**PHOTOGRAPHING WOUNDED ANIMALS.**—"English Sportsman" writes to the "Spectator" to protest against the habit lately come into vogue of photographing wounded animals for the purpose of publishing pictures of them in books of travel and sport. "I am informed, on good authority, that animals are often kept in this condition for long periods until they can be photographed. The reason for it is doubtless in order that the shape of the animal may in some measure be retained, and a little life put into the illustration. And life is put into it, consisting of a piteous appeal in the eyes of a dying creature. I am even informed that animals are purposely wounded instead of being shot outright in order that the desired effect may be attained. This fashion—for that is what it is becoming—is not sportsmanlike. It is no use scientifically, and it is brutal and a bad example, and I hope that, through public opinion, it may be stopped."

## Correspondence.

\* \* \* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### PATENTS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—The dominant factor in Colour Photography finds it necessary to call me to order, I am therefore compelled to Reply—ergo beg to be excused for the Echo.

I cannot recollect having come across "Compensation for Refraction" except when recommending parallel prisms, in any of Mr. Ives' English Patent Specifications; perhaps Mr. Ives will enlighten His English Admirors by telling them, where to find it; but if he has taught it, his teaching seems to have been lost this side of the pond.

If Refraction Compensation has been taught by Mr. Ives as being a necessity in Three Colour Cameras in which the conical Rays are coming from One Optical Center, how does it happen that people with knowledge put their Name to such Construction as given page 854, 856, Br.J.Ph. Alm. 1906; or to, last year an English "Encyclopaedia" in Photography giving the exact measurements for such a Camera; or to, also Prof. Miethe's in his "Driefarbenphotographie nach der Natur" 1904 page 27, he also giving a Camera with two Reflectors; but nowhere is a suggestion, that something has to be compensated, if such a Camera is intended to furnish

three Negatives of same size,—nowhere—Mr. Ives—how do you account for this Ignoring of your teaching after years.

Mr. Ives says, he has corrected the Reflected Images with the insertion of slanting Colour screens (without disclosing their purpose in 1894 till 1899!) the latter, I understand, more or less parallel with the Reflectors; and that, he advances as a complete compensation for what will distort the reflected Image also.

I do not distort the Reflected picture, but I compensate after the Refraction has taken place, and I compensate in such a manner, that all sides are equally shortened and by placing the Focus at a further Distance, I arrive at the proper solution of having all pictures equal and properly compensated. Result: If I copy a Square it will be square, by Ives System the copy will show an oblong, the difference is about Half the Glass thickness of a Reflector.

A Camera like Patent 4290 '05 and shown page 856 in Br.J.Ph. Alm. 1906, will give three pictures in three different sizes, and if in this Camera we insert a Compensator (a plain Glass or colour Screen à la Ives) parallel with the Reflector "A" and above the Lens, then I think it will fairly represent (I quote from Memory) the U.S. Patent 635,253, quoted by Mr. Ives; I assert a Construction like this can have only two Negatives of same size and the third Negative at the back will still be shorter from Top to bottom in comparison with the other two. Both these Systems are therefore only "Viewing Instruments, Kromoscopes," and are no good for Colour photography in Pigments.

Ives introduced the prismatik Reflectors with the idea to throw off the Double images, caused by Double reflection, but nowhere does he introduce them in his Specifications as compensators for Refraction.

If Mr. Ives knew all the "ins" and "out" of Reflection and Refraction, why did he not compensate his Camera 635,253 1899 all through? Ives has done in compensation also 630,442 1900 and 703,929 1902 U.S., but both of them do not show balanced compensation or three Focus planes of equal size; how in face of his own Works and Patents as Evidence, can he claim Refraction-Compensation as his own since 1894; his "own" Refraction-Compensation evidently refers to something else.

My Fig. 11 given in the Abstract in Patent News 2. Aug. 1907 Br.J.Ph. is the simplest Form for a Reflector Camera, holds the simplest and the correctest Refraction Compensator, and is devoid of any delicate Mechanism or any expensive insertion, permits a View of up to 30°, and it is impossible to put it in a more useful and compact form; if Mr. Ives had invented it, I should envy him for it. I am pleased to say, there is really nothing in common with any of Mr. Ives published patents to the best of my knowledge, and I think to his own Wonderment as his letter testifies.—Yours truly,

Brighton 1/9 1907.

OTTO PFENNINGER.

[At the particular request of our correspondent, we allow his letter to appear precisely as received.—Eds. B.J.]

#### REFLEX CAMERAS.

To the Editors.

Gentlemen,—Apropos of the recent exhibition, which I unfortunately could not visit, I venture to inquire whether there is yet a decent reflex on the market for amateurs. The Pressman has to use the most efficient tool he can get, regardless of its weight, cost, and inconvenience. The amateur is not bound to make a beast (of burden) of himself. Though I have never exhibited but once (officially, and getting a medal), I have practised photography in most of its phases since about 1870 continuously, making my own dry plates of various kinds in the early days. Apparatus has always interested me, but I am unaware of a really good reflex. A camera limited to one focus does not constitute a really good one. This cuts out the cheaper forms. Neither does a camera costing £30 meet the case, for the cost is unreasonable (I speak as an amateur mechanic and joiner), and the tool is a burden to boot. I call it a burden, because of the reversing back and consequent weight. For an ordinary camera the reversing back is, in my opinion, a cunningly devised snare for inducing people to lug about cameras far bigger and heavier and more costly than they need. For me the ideal camera is one taking a long plate, not a square one, and simply turning on its side where the picture is wanted vertical. If you turn a reflex on its side the

mechanism works quite differently, and if you want to put it on a stand or table you find (in nearly all cases) that you cannot on account of the numerous knobs and handles. The focal-slutter I consider a very doubtful advantage. The leather cover so much in vogue, is a mistake in the tropics, if not everywhere, especially on metal cameras. The leather and the glue become by mould and mildew. Metal does not hold to glue at the times, still less when great changes of temperature cause expansion and contraction. The glue also acts on the aluminium producing lumps of white powder, and eventually holes. Pos size is about the largest focal-plane reflex that is not a burden; this size is only recently made by one or two firms. It is also the largest size in which the film packs can be relied on to work without hitch. The camera I should like would be a reflex about 7½ taking either one picture or a pair of stereos, with lenses of 5, 5 inches, 10 inches, and 16 inches focal length, also the "A." I hope for the day when we shall get an "Adon" with rapid definition, and covering power enough to enable us to dispense with other lenses, but that day is not yet. The ideal amateur size for me is 8 x 5 for stand work, but for hand work the lenses and conditions of working so large a size introduce difficulties. A card camera (cut films) will go into the pocket as easily as a quarter plate, and so gets carried when a bigger camera would be left at home, but it is hardly large enough for the amateur's principal work.

It may be a new and interesting matter to mention that some of our celluloid film negatives that have been stored away for years have now adhered together, and become utterly ruined, the surface of one negative adhering to the celluloid of the next. Moral: Lay up paper between.

Indian Forest Service

[The answer to our correspondent's letter is our issue of July 1907, in which practically every reflex camera on the market is described. Our correspondent's letter is yet another instance of dictum that there is no best camera, and that it is impossible for one worker to argue from the personal preferences of another. We ourselves cannot concur in certain of our correspondent's criticisms of existing types of camera. Most certainly we are with him in requiring a double extension of camera, but we would not dispute with the reversing back of a reflex, for the very sufficient reason that it seems to us, that we should be sacrificing the facility which a reflex provides of photographing the subject certainly and accurately on the plate. It is significant that one maker of standing, in providing a non-reversing reflex, does not leave the user to focus with the camera turned on its side, but provides a scale and finder, attaining great portability at the sacrifice of efficiency. Moreover, not all reflex cameras have knobs projecting in a way to interfere with their use on a table. Our correspondent cannot be thinking of the reflex type of camera, when in his penultimate paragraph speaks of one of postcard size going into the pocket. Such an instrument has yet to be made.—Eds. "B.J."]

"BULLETIN OF PHOTOGRAPHY."—A "weekly magazine for the professional photographer," is the description of itself which our American contemporary prints on its front page. In typography and printing it is on a par with the excellent production of American technical journals. The text of the journal, which is agreeably interspersed with advertisements, is evidently representative of the professional feeling of the American professional, from the prominence it gives to the Convention season, which is in full swing in the State of New York in August and September. The "Bulletin" also shows its interest in providing plenty of news items, and is evidently aiming at a wide reading matter of the "enthusiastic" character which appeals to the American reader. The new journal is edited by Dr. Bartlett, and published by Frank V. Chambers, 606-608, Sansbury Street, Philadelphia.

RUGBY PHOTOGRAPHIC SOCIETY.—The annual exhibition will be held in the Benn Buildings, Rugby, from November 12 to 16, inclusive. There will be five open classes, in each of which a bronze medal and a picture of the catalogue, value of 12s. 6d., selected from the exhibition, will be placed at the disposal of the judge, the Rev. F. Lambert, M.A., for award. Entries close October 29, and entry lists and full particulars respecting the exhibition may be had from Hon. Sec., Mr. R. H. Myers, 13, Bridge Street, Rugby.

## Answers to Correspondents.

All matters intended for the text portion of "THE JOURNAL," including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Wick, 84, Union Road, Nottingham. Photograph, Group of Notts County team, 1907.  
 Stainer, 2, North Parade, Taunton. Photograph of an Engraving of the Queen and Somerset Stagbonds.  
 Whitaker, Post Office, Bolton Abbey. Six Photographs of the Interior of the abbey, Bolton Abbey.

**HIDE TONING OF P.O.P.**—I should be greatly obliged if you would answer me a few questions. I have been trying the sulphide toning for P.O.P., and met with very fair success at first, but now it is a complete failure. My methods of working are the same as were published in the "British Journal" on January 12, 1906, recommended by Mr. A. J. Jarman, and also in the "Almanac" for 1907, recommended by Mr. R. E. Chesterman. Enclosed are five prints on Wellington's paper, numbered 1, 2, 3, 4, and 5. No. 1 was placed direct in fixing bath and toned with sodium sulphide. No. 2 was placed in solution of salt (2 oz. in 20 water), fixed and toned as for No. 1. Both results are all that can be desired. No. 3 was placed direct in hypo, and showed yellow high-lights before toning. No. 4 was placed in salt and showed yellowness after toning. No. 5 placed direct in hypo at exactly same time as No. 4, fixed and washed exactly the same time in separate dishes, and toned in same bath. Result: Whites clear, but full of yellow spots, as in No. 4. The fixing bath is made for each batch, the strength being: Hypo, 3 ozs.; water, 20; and timed for fifteen minutes. Each batch of prints is tested for the last trace of hypo with the potass hydrate and permanganate test. Sometimes the prints, being "white as crystal" after toning, turn yellow after alum, but formalin does not seem to affect them. As I have been successful the fault must be in the working, so I should be glad if you will answer the following questions:—(1) Where, in your opinion, does the fault lie? Is it possible that the hypo or salt is contaminated, or even the paper, by the sulphur fumes? (2) Do you think it possible to be successful with quantities where, owing to limited space, the toning has to be done in the fixing and washing room, and where the sulphur fumes are sure to penetrate to the changing-room, and so where the hypo is stored? (3) The cause of the fading and staining of the high-lights, as in No. 3 print, during fixing? (4) Is it possible to use alum after the sulphide? And (5) the cause of the spots on Nos. 4 and 5. I have tried paper of nearly all the well-known makers, the results being the same.—**SULPHIDE.**

We have never recommended the sulphide process, as the results, in our experience, have been often erratic. (1) The variations are due most probably to access of acid to the hypo in some way, possibly from the small proportions of free acid in the paper. We suggest the use of the salt and carbonate bath, page 778 of the "Almanac," which we see has not been used at all. (2) Sulphur fumes which reach the paper at any stage before it enters the hypo will certainly lead to yellowing. (3) We can only suggest that the bath had become acidified by a number

of prints being fixed in it. The remedy is to add a little carbonate or bicarbonate of soda to it. (4) Yes, with a wash between. (5) We have not seen spots of this kind, and find it difficult to suggest a cause other than particles of rust in the water, though the salt should prevent their effect. We advise you to try a little carbonate of soda in the hypo and salt bath.

**COMBINED BATH.**—(1) I have used a combined T. and F. bath for some years—hypo and sulphocyanide of ammonium only—adding gold as required. I am satisfied as to permanency of prints thus toned, but should be glad if you would tell me cause and how to avoid dirty yellow tint in high-lights, as seen in scrap of print enclosed; it is only now and again that this happens. (2) When I tone and fix a batch of prints in new bath, next day solution is too dirty to be again used, though, of course, far from being exhausted. Can you give formula for combined T. and F. bath, where faults I have pointed out are not so likely to occur?—**COMBINED BATH.**

(1) Due to over-working of the bath. We advise you to take bath containing enough gold for prints to be toned, and not tone more without addition of gold. (2) If you have no other fault than this we advise you to stick to the bath, which is less open to objection than many others. A very good and similar formula.

### STOCK SOLUTIONS.

No. 1.—Hypo, 12 ozs., dissolved in water, and made up to 2 pints.

No. 2.—Ammonium sulphocyanide,  $\frac{1}{2}$  oz., made up to 5 ozs.

No. 3.—Lead acetate,  $\frac{1}{2}$  oz., made up to 5 ozs.

No. 4.—Gold, 15 grs., made up to 5 ozs.

Take:—No. 1, 7 ozs.; No. 2, 1 oz.; No. 3, 1 oz.; No. 4,  $\frac{1}{2}$  oz. Wash thoroughly, tone and fix in the above bath, and finally wash in running water for about one hour.

**TONING BATH.**—I am enclosing a small bottle of toning bath. I should be glad if you can tell me the cause of it going this colour. It is the ordinary P.O.P. bath (ammonium sulphocyanide). I have tried with both hard and soft water. It acts all right the first time, but the next day I find it this colour and no use.—**G. S. P.**

Soft water is very likely to throw down the gold—which is what has taken place—owing to the organic impurity usually in it. Deep spring water is almost always better, and if boiled for ten minutes, allowed to cool somewhat, the sulphocyanide dissolved, and then the gold (in small doses of solution) will give a bath which will retain its toning powers for some days, though not indefinitely. If your water supply will not enable you to do this, there is nothing for it but to use distilled water.

**IRON.**—We doubt if there is much in the idea as a saleable article. It is a poor camera nowadays that has not a short focus movement sufficient for all ordinary work. We suggest that before spending any money on it you obtain the views of one or two leading makers of apparatus as to the demand for such an appliance.

**W. CHARLES.**—We do not supply books. Apply to your dealer or to Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C.

**AGREEMENT.**—I am an assistant photographer at the above-mentioned town, and in November, 1897, my late employer offered to teach me the business on the following conditions—viz., "that I should not on any account have any connection with another photographer, or commence business for myself within a four-mile radius, four years from the severing of the connection between us." He first employed me November, 1897, as above mentioned, and on July 20, 1902, dispensed with my services. A year later he bought a business at —, and wrote me offering a position (which he led me to think was permanent and greatly to my future betterment) at the — studio. He, however, sold the latter about fifteen months after, and asked me to stay with purchaser. Could he prevent me opening business in this town, as I signed nothing when I returned? I am very anxious to know, as I am well known here. You will see we parted five years ago, in the first instance.—**F. B.**

The original agreement was obviously binding on you only in the first instance, and not in the second. Unless a second arrangement was entered into, there is nothing to prevent your opening business.

**E.**—It is out of our province to tell you how you can avoid paying

for what you purpose to buy. You had better apply in some other quarter.

J. H. P.—Indentures must be stamped with a 2s. 6d. stamp, otherwise they are not binding.

DUSTING-ON PROCESS.—I am pretty familiar (by reading) with the method of producing burnt-in pictures by the dusting-on process, but I have an idea that I have read of a method of making them by what is analogous to the carbon process—that is, the pigment in the tissue is a vitreous one, which can be burnt into the enamel or porcelain, as the case may be. Can you tell me where I can get such tissue, as I do not see it quoted in any of the lists I have?—ONE WHO WANTS TO TRY IT.

No such tissue is on the market, and we much doubt if any of the manufacturers would make it to your order. It is true that ceramic pictures can be, and have been, made by this method, but not very successfully. The difficulty is that when the pictures are "fired" the gelatine splits off taking the vitreous pigment with it. If you are desirous of producing ceramic pictures, we should recommend you to adopt the powder process, which is the one universally employed by those who make them commercially.

ENAMELLING PRINTS.—We do a good number of enamelled prints—that is, enamelled with collodion in the usual way. Using —'s enamel collodion, the pictures are all right, and we get extra prices. But some of our customers have complained that the surface of the collodion is so easily scratched, and then becomes unsightly. We have been told there is a method of enamelling pictures with thin celluloid, which is much harder and does not scratch like the collodion. Can you kindly tell us how it is done?—PROVINCIAL.

It is done in this way: The picture is first soaked in alcohol—methylated spirit will do—then drained and placed on a piece of thin transparent celluloid. A heated, heavy, iron roller is then slowly passed over, which causes the celluloid to adhere. A special roller is required for the purpose. Fallowfield's make a specialty of the necessary materials for this class of work. We should advise you to get their price-list of the things required.

RIGHT TO PUBLISH.—A few weeks ago I took two photographs of the interior of a village church not far from here and published them, with one of the outside, in the neighbourhood. Last week the vicar came to me and was very indignant about it, as I had not asked his permission, and told me that unless I immediately stopped the sale he would consult his solicitors and take proceedings against me. Will you please tell me if he can do what he threatens, and how I should proceed if he does, as I do not like to stop the sale, as the photos are selling well as postcards?—C. J. W.

Our advice is to let the vicar consult his solicitor, who will tell him that he has no power to prevent the sale of the pictures. It is merely bluff on the part of the vicar, as he must, or should, know that he cannot interfere with the sale of the pictures.

DEFECTIVE NEGATIVE.—We enclose herewith a rough specimen print from a negative taken by us recently, taken at seven o'clock in the evening—dull, misty rain hanging about. Ross W.A. doublet lens. This print is the first exposure. Second exposure, without altering the camera in any way, except to reverse slide, is quite perfect—same kind plate. Should be glad to know your opinion as to cause of halation.—BROMIDE.

The trouble is due, we think, to thin coating of the plate towards one end, which has caused the peculiar appearance.

H. F.—1. See our issue August 30. 2. It would be very much better to use a diffraction grating as regards the distribution of colours, but there would be a difficulty in getting rid of the central white image, and there is, of course, considerably greater loss of light than with a prism. 3. The patent you refer to is No. 24,234, 1902, so that we have not yet reached it.

COPYRIGHT.—We shall be glad if you will kindly say what the law is on the following question: In the absence of any agreement, if a firm of press photographers employs a man at a weekly wage to photograph events or happenings for the Press, is the

copyright of his pictures the property of his employers?—

The copyright is vested in the employers.

COPYRIGHT.—If A obtained a photograph from me with intent publishing, and on finding it copyright declined (by let publish (but did not return photograph), and subsequently reproduces a number of copies and circulates to different who reproduce them under A's name, does he infringe my right? I considered my offer closed after his refusal to copy. Does permission given to one give him the liberty to duplicate in this manner? If so, there is little use in registering a photograph copyright.—CARBON.

The newspapers in which your photograph has appeared infringe your copyright, as has also A by circulating copies. A can act as he has done with impunity only in the cases of subjects in which no copyright subsists.

DEVELOPER FOR BLACK AND WHITE.—I should esteem it a favour if you could inform me of a developer to get a good hard negative for titles for postcards. I have had a dozen titles set up printed (black on a white card), have used several plates but cannot get the desired result.—W. T. Cook.

A suitable formula is:—

Hydroquinone .....	130 grains.
Soda sulphite .....	6 grains.
Formalin (commercial) .....	3 drachms.
Water .....	20 ounces.

Use as above. It acts slowly, but without veil. Are you aware of a "process" or "photo-mechanical" plate? You should use it for the maximum clearness of the lines, but the above developer will improve your results in any case. Another formula acts quickly and which in conjunction with Farmer's reducer applied afterwards, will give very clear lines, is:—

A. Hydroquinone .....	160 grains.
Sodium sulphite .....	2 ounces.
Citric acid .....	60 grains.
Potass bromide .....	40 grains.
Water .....	20 ounces.
B. Caustic soda .....	160 grains.
Water .....	20 ounces.

A, 1oz.; B, 1oz.; water, 2oz.

ARISTO'S.—I wrote to Messrs. Dawbarn and Ward, Limited, asking for two ago for the "Photo-miniature" (How to make Aristos). It is sold out. 1. If there is another book, please give the title. 2. Where to get it, with price. 3. If no book, what paper is there on the subject?—J. Cook.

If by Aristos's you mean prints in collodio-chloride paper, we can best refer you to articles in the "B.J." November 10, 1901, which you will find abstracted with others in the "C. Almanac," p. 786. There is no special book on collodion printing.

G. W. S.—Certainly we should call the photographs "good," those marked A and B very good of their kind. We have no objection, and suggest that a larger picture of the diver on the plate is desirable, though we are fully aware of the difficulty of the work.

\* \* \* NOTICE TO ADVERTISERS.—Blocks and copy are received for the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

## SUMMARY

**Colour Photography.**—We publish the first account of important advances in the screen-plate, one-exposure method of colour photography. The process known as the Warner-Powrie permits of the printing of colour negatives and of the preparation of a set of continuous-tone, colour-sensation negatives from the single exposure in the first instance in an ordinary camera. The process requires no registration at any of its stages, and further supplies a means of using the bleach-out "Uto" paper. (P. 688.)

**Colour Photography.**—A detailed description of the method followed in making the screen-plate for the one-exposure method of Hauron, to be issued commercially as the "Omnicolors," is published on p. 696.

**Colour Photography.**—Professor Cajal has published some practical details of his working of the Lippmann process. (P. 691.)

**The Exhibition Season.**—A list of exhibitions already announced appears on p. 695.

**The Photographic Salon** opens to the public to-day. A first impression of the pictures and their hanging appears on p. 692.

**The special adaptation** of the card-index system to a photographer's system was described before a recent convention by an American professional, Mr. G. W. Harris. (P. 693.)

**We draw attention** to some of the provisions of the Factory Act which require to be observed in photographic establishments. (P. 687.)

**A serious accident** in the exhibition of cinematograph pictures took place at Newmarket last week, one member of the audience sustaining injuries which proved fatal. (P. 686.)

**The full prospectus** of photographic and process instruction at the Manchester Municipal School of Technology has been published. (P. 700.)

**A curious case** concerning the construction of an overhead bridge between two buildings of a photographic factory is reported under "Commercial and Legal" intelligence on p. 700.

## EX CATHEDRA.

### A New Prospective in Colour Photography.

We ask a very careful reading of the article, "Latest Developments in Screen-Plate Colour Photography," which appears on another page. In giving the first account of the progress made in the Warner-Powrie process it has been our desire to state the plain facts, as they have come to our knowledge, in such a way as to allow our readers to judge for themselves the part which the process is likely to play in the practice of colour photography. But a close acquaintance with the methods and results of the new process, with the successive steps which have been taken to bring it from failure to success, and, lastly, with its unassuming originators, makes it impossible to commit to paper a quite unimpassioned recital of a veritable scientific triumph, which is at the same time a commercial asset and of far-reaching importance in the graphic arts. The description, as we have said, requires a careful reading; if we now enumerate what has been accomplished it will perhaps be seen that it also deserves it.

\* \* \*

### The Warner-Powrie Process.

The manufacture of a screen-plate of a finer ruling than is actually necessary has been reduced to a factory system calling for very little skilled labour, and capable of adjusting itself to alterations of temperature and humidity of the air. With the emulsion-coated screen-plates a negative in colours (complementary) is made at one exposure in an ordinary camera, and can be at once converted into a positive in colours. Either, however, may be copied on to another screen-plate, and any number of brilliant positives obtained, the complementaries in colour and in light and shade of the negative. This "colour printing" can be done without register in an ordinary printing frame in an ordinary dark-room. Further, from the first colour negative on the screen-plate a set of three full-tone colour-sensation negatives can be made by an equally simple series of printing in a frame, and, once more, without register. We might name one or two other side issues of the method, but the above description will suffice to show the commercial possibilities of the process. A hint of some other facilities provided by the Warner-Powrie method may be gathered from the article on another page.

\* \* \*

### Warner-Powrie Literature.

Less has been written of the progress of the Warner-Powrie process during its ten years of development than of many another method which in that period has had its little day and ceased to be. In the "B. J. Almanac," 1906, page 863, is a brief reference to the Florence screen-plate

from the "Illustrator," a process journal edited at that time by Mr. A. C. Austin, to whom Mr. Powrie had shown some of his early results. Some short notes on the manufacture of the screen-plates were contributed by Mr. Powrie to Penrose's Annual for 1905-6 ("B. J. Almanac," 1907, page 850), and in June, 1906, the English patent specification of the process was issued. With the exception of an account of the process which M. Quentin contributes to his journal, "La Photographie des Couleurs," these references constitute the chief published information in regard to the process, which is probably better known, even from these meagre details, in England than in America. Great interest is certain to be aroused in the results produced by the almost incredible procedure, and we may therefore say, without committing any breach of confidence, that Miss Warner and Mr. Powrie are sending a selection of earlier and later results to the exhibition of the Society of Colour Photographers, which opens on September 30.

### Intensifying Lumière "Autochromes."

The "Amateur Photographer," which has in the past consistently discharged its duties to its readers in keeping them *au courant* with progress in colour photography, not excepting the now much-talked-of Lumière process, points out in its issue of September 10 an alleged error in the formulae for intensifying the Lumière plates. Our respect for the well-informed notes which our contemporary has published compels us to say that in our own experience the formula for the F pyro solution of 3 gms. pyro and 3 gms. citric acid per litre, as given by the Lumières (not 30 gms. citric acid, as stated by our contemporary to be correct and that actually employed in the commercial Lumière carton), works efficiently in the time specified in the Lumière instructions. We have made up our intensifier according to this formula (of 3 gms. of each), and have usually found a minute to two minutes required for intensification, whereas a tenfold proportion of citric acid would retard intensification considerably and would accentuate the frilling of the plates, which is apparently very common.

### Celluloid Accidents.

On Saturday night last an alarming accident happened at the Town Hall, Newmarket, during a cinematograph exhibition. One person was killed and many others seriously injured. It appears that the apparatus was overturned by people leaving during the interval by the main entrance, close to which it was planted. Some of the films then took fire, the cry of fire was raised, and the usual

stampede took place, with injury to several persons in the rush for the doors. The fire, which was confined to the apparatus and the woodwork near, was quickly put out by the hose within the building. It was pretty obvious that the restrictions placed upon cinematograph entertainments by the London County Council are not enforced in Newmarket, or this accident would not have occurred. Another accident reported last week is attributed to spontaneous ignition of celluloid. It appears that a lady was sitting in a garden at Crowborough, Sussex, when her friend noticed that a celluloid comb in her hair was flaming, having been affected by the rays of the sun. The comb was quickly removed, and no injury was sustained. One has been continually reading for some years past of someone or other has invented a substitute for celluloid that is not inflammable, but it has not yet been heard of in practice. As we have said more than once before, a substantial fortune awaits the inventor of a celluloid substitute for it, which is non-inflammable, while retaining its utility.

### Oil

#### Printing.

It has several times been pointed out that it would be very desirable to give a new name for such productions as oil prints, on grounds that all essentially photographic features vanish in the pigmentation process. In the hands of people who do not produce something different from a photograph, an oil print can speedily lose all its photographic quality, and those who can see no art in purely photographic work, seem to find a very desirable characteristic of the oil process. The majority of persons, however, and especially those who have been trained as artists and are artists by profession, do find many artistic virtues in straightforward photographs, and it is rather unfortunate that so many seem to think that all photographic quality must necessarily be lost in oil printing. In the majority of results that have been shown, all such quality has been deliberately obliterated, but it is by no means essential that this should be so, nor is it at all difficult to preserve it. And from our own experience it is quite possible to preserve the best qualities of both the photograph and the pigment process. One of the good qualities of the process is the surface texture. This, in careful and practised hands, is a very fine granular texture of just the kind many have long wanted to produce with rough papers. Our mind it is better than the paper texture, for it can be modified in parts, and so does not become so monotonously uniform. Another good quality of the oil process is the fact that it allows us to make very readily on print the slight alterations in emphasis and values

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

SCREEN-PLATE THREE-COLOUR PROCESSES and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the next edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

marily we have to make by dodging in printing or  
ing on the back of the negative. Such slight modifi-  
cations and also spotting and retouching can be done with  
greatest ease on the oil print, whereas in the ordinary  
it is by no means easy to "dodge" the negative to  
the right extent. To speak quite frankly on the  
subject, we have a very small opinion of the art value of  
usual oil print that is neither a good photograph nor  
good oil painting, and we feel pretty certain that this  
of production will not be in favour very long. On  
the other hand, we feel that the oil process has features of  
undoubted value, and we strongly advise photographers  
to turn their attention to its possibilities in the way of  
light photography.

### of dividuality.

The admiration that some people pro-  
fess for hybrid productions, such as the  
oil prints that we have referred to as  
neither good photographs nor good paintings, is obviously  
in many cases to want of sufficient knowledge of either  
the art or to be able to detect faults. The worst  
error will pass as verse to the man who knows no  
body. But more generally the cause of the admiration  
may be traced to the heretical worship of so-called in-  
dividuality. If it is possible to recognise the handiwork  
of Mr. Jones in his productions, then Mr. Jones's  
work has some claim to be considered artistic. That is  
the result of the heresy. Another, and a necessary  
consequence, is that all art productions must, of course, betray  
the handiwork. All this is directly opposed to the great  
aim of the true artist, which is that his work shall appear  
something superhuman, and altogether beyond a mere  
accomplishment. He never reaches the ideal, but  
his attempt to reach the ideal of perfection that stamps  
as an artist, while it is by his sticking-places that we  
recognise his individuality. If his sticking-places are  
places, then they are places of honour, and this kind  
of individuality is virtuous and honoured. A mere trick  
of brush or of technique, or a dodge as regards materials,  
mark of individuality in one sense, since it is a means  
of identification; but it is no virtue, though the innocent  
times take it for one. Has it never struck photo-  
graphers that the feature of photography that most appeals  
to the artist is the purely impersonal touch of the  
camera and the extraordinary superhuman accuracy and  
fidelity of the delineation? These are just the features  
despised by the would-be artist photographer, because  
they are features of a would-be artist and not a real one, but they are  
features most appreciated by the real artist because  
they represent a sort of approach to the absolutely imper-  
fection that is his ideal.

### FACTORY AND WORKSHOPS ACT AND PHOTOGRAPHERS.

There are occasions when it falls to our lot to administer  
justice to photographers seeking encouragement or  
protection in practices which are often illegal, and some-  
times immoral. Among these none are perhaps more fre-  
quent than those whereon we are solicited to sympathise  
with some proprietor of a photographic establishment  
who has addressed to him an (alleged) unreasonable  
demand from the factory inspector of his district as to the  
conditions made for his work-people or the hours which  
they have been employed. Our friend will sometimes  
remark that if these interferences with his liberty  
be, the economical conditions under which he obtains  
his labour will be disturbed, and good-bye to a substantial  
income from the sale of photographic art. We admit the  
force of the objection in these hard times, but nevertheless

the law has penalties for those who offend its provisions,  
and nothing will be gained by shutting the eyes to them.  
On this account it may be well for us to draw attention to  
the provisions of the Factory Act which bear upon photo-  
graphic establishments; in doing which we would point out  
that the Act is calculated to benefit equally employers and  
employed, for the latter can discharge their duties satis-  
factorily only when they are properly housed and placed  
in healthy surroundings, and not subjected to excessive  
spells of labour. For the employer to regard the Act as  
a tax which he must pay without securing any return is,  
we think, a mistaken view, as a study of the provisions of  
the Act will show.

The first question which arises in the mind of a photo-  
grapher who has received an official reminder of the Act,  
or of his infringement of a provision of it, is that the work-  
rooms of a photographic business cannot be looked upon  
as a factory; but the comprehensive wording of the Act  
leaves no doubt that they are actually so regarded. A  
workshop as defined by the Act means "(a) Any premises  
or places named in part two of the sixth schedule of this  
Act, which are not a factory; and (b) Any premises, room,  
or place, not being a factory, in which premises, room, or  
place, or within the close or curtilage or precincts of which  
premises, any manual labour is exercised by way of trade,  
or for purposes of gain, in or incidental to any of the follow-  
ing purposes, namely—(1) In making any article or part of  
any article; or (2) The altering, repairing, ornamenting,  
or finishing of any article; or (3) The adapting for sale of  
any article; and to or over which premises, room, or  
place the employer of the persons working therein has the  
right of access or control." After reading this no one need  
be in doubt as to whether photographic work-rooms are  
workshops within the meaning of the Act.

This fact having been digested, it may be well for the  
photographer to become familiar with one or two other  
regulations of the Act. It is necessary that an abstract  
of the Act itself be affixed at the entrance of the workshops,  
or such other parts as the factories' inspector may direct,  
so that the employees may read it and make themselves  
fully acquainted with its enactments. The object of this  
is that the employees may be fully apprised of the law  
relating to the conditions under which they are employed.  
For the non-display of the abstract the occupier of the  
workshop is liable to a penalty not exceeding forty  
shillings.

By Section 119 of the Act, an inspector has power "(a)  
To enter, inspect, and examine at all reasonable times, by  
day and night, a factory or a workshop, and every part  
thereof, when he has reasonable cause to believe that any  
person is employed therein, and to enter by day any place  
which he has reasonable cause to believe to be a factory  
or workshop. . . . (f) To examine, either alone or in  
the presence of any other person, as he thinks fit, with  
respect to matters under this Act, every person whom he  
finds in a factory or workshop. . . . (4) Where an  
inspector is obstructed in the execution of his duties under  
this Act, the persons obstructing him shall be liable to  
a fine not exceeding five pounds." From this it will be  
seen that the inspector has the right to ask any questions  
he chooses of any of the employees with regard to their  
conditions of working, hours they are working, or any other  
relevant matter.

The term "women" applies to all females over eighteen  
years of age. The term "young persons" applies to all  
under the age of eighteen. It should here be mentioned  
that it is illegal to employ any "young person" under the  
age of sixteen, unless the employer has ascertained from  
the certifying surgeon of the district that such young  
person is fit for the employment.

The period of employment, except on Saturday, may

begin at six in the morning and end at six in the evening, or it may begin at seven in the morning and terminate at seven in the evening, or begin at eight in the morning and end at eight in the evening. One hour and a half must, however, be allowed for meals, and no woman or young person must be employed continuously for more than five hours without an interval of at least half an hour for meals. Furthermore, the meals must not be taken in the workshop. On Saturdays the employment may be from six in the morning till two in the afternoon, or from seven till three, or from eight till four. But in all cases half an hour must be allowed for meals. No woman or young person must be employed in a factory or workshop on Sundays.

In England there must be allowed as whole holidays Christmas Day, Good Friday, and every Bank Holiday, unless in lieu of any of these days another whole holiday or two half holidays, fixed by the employer, are allowed. Eight half-holidays a year, fixed by the employer, must be given, but a whole day, also fixed by the employer, may be allowed in lieu of two half holidays. At least half of the whole holidays or half holidays must be allowed between March 15 and October 1 in each year. In these holidays Christmas Day, Good Friday, and Bank Holidays do not count—they are in addition to the above. A half holiday must comprise at least one half of the period of employment on other days than Saturdays. These being holidays prescribed by the Act, no deduction of wages must be made for them.

In addition to the abstract of the Act before mentioned there must be posted up in the workshop details of the

hours of employment, times for meals, holidays, etc., which must be signed by the owner of the workshop. With the sanction of the Secretary of State—whom the local inspector of factories represents—another day in the week may be substituted for the Saturday half holiday.

Women may be employed overtime, as from six in the morning till eight in the evening, or between seven in the morning and nine in the evening, or between eight and nine in the evening, if they are paid in accordance with the following, Section 49 of the Act:—“(a) There must be allowed every woman for meals during the period of employment not less than two hours, of which half an hour must be after five o'clock in the evening; and (b) A woman must not be employed in the whole for more than three days in any one week; and (c) Overtime employment under this section must not take place in any factory or workshop on more than thirty days in the whole in any twelve months, and in reckoning that period of thirty days, any day on which any woman has been employed overtime must be taken into account.” When overtime is to be worked notice must be given to the inspector.

Section 137 of the Act is to the effect that where a person is employed in a factory or workshop, contrary to the provisions of it, the occupier of it is liable to a fine not exceeding three, or if the offence was committed during the night, five, pounds for each person so employed.

The above constitute the most important provisions of the Act as it may be applied to workshops of the kind which are to be found in photographic establishments. There are some minor enactments, to which we may refer at a future opportunity to refer.

## LATEST DEVELOPMENTS IN SCREEN-PLATE COLOUR PHOTOGRAPHY.

[In publishing the following account of the progress made in collecting all the news relating to colour photography in the *THE BRITISH JOURNAL OF PHOTOGRAPHY*, yet we believe we are giving information as to this new departure which has become available

THE greatest interest is bound to be created in the announcement of the progress made in the method of colour photography in which the filters are distributed in the plate itself. Up to now the Lumière “Autochrome” plate has monopolised public attention to such an extent that it is easy for those who have not followed the work of the past few years to associate such one-plate processes exclusively with it. There is, however, to be shortly available a new screen colour plate which is a further development of the original Joly linear method, but embodies advances of such importance in this latest of colour photographic systems that an account of what has been accomplished appears to be called for. It is scarcely necessary to explain that the Joly process, as it has hitherto been known, consists in the use of a filter of fine ruled bands, alternating red, green, and blue, which is placed against the sensitive surface of a panchromatic plate, and exposure made through it. From the colour-record negative thus obtained a positive is printed by contact on a transparency plate, which positive transparency, on being bound up in register with a ruled screen, similar to that used when making the exposure, reproduces the colour of the original object. It will be within the recollection of many persons that this system, as first worked out by Professor Joly, of Dublin, and afterwards by the late Mr. MacDonough in America, proved capable of being easily employed once the screen plates had been produced, but that the regular manufacture of the screens on a large scale proved a task beyond the powers of both the com-

mercial undertakings which were formed to work the process. Moreover, even with a perfect screen, there were certain obstacles in the way of absolute certainty—chiefly the difficulty of securing uniform contact between the screen and the sensitive plate in the camera—which limited the application of the process in practice. It has been left to Mr. John H. Powrie and Miss Florence Warner, of New York, to successfully combine the screen with the plate, to perfect the manufacture of the screens, and to induce important developments of the process which enormously increase the possibilities of the one-plate linear colour system. In short, to briefly anticipate what we have to describe, the Warner-Powrie process, as it is to be called, (1) combines a linear screen with the plate, forming a “screen plate” ready for exposure, at a price which, we are informed, will not be much greater than that of ordinary plates; (2) provides means of duplicating the colour results; and (3) permits of a so-called full-tone negatives, that is without the linear ruling, being prepared from the single negative, from which set prints of any size by the pinatype or other process can be prepared.

### A Factory Process.

The series of experiments which has now led to a successful issue was commenced by Mr. Powrie ten years ago, the greater part of which time has been taken up in making the experimental success of the first year practicable upon a commercial scale of any required magnitude. It would take too long

scribe the chemical and mechanical expedients, chiefly the filter, which have been tried and abandoned; but Mr. Powrie and Miss Warner have together worked out a manufacturing process which they have already proved to have nothing in common with its predecessors, and is, in fact, an original application of Du Hauron's principle to commercial industry. Some particulars of the process, in Mr. Powrie's own words, were quoted from the "Process Year-Book for 1905-6" in THE BRITISH JOURNAL OF PHOTOGRAPHY of 1905, p. 1,029; but if the process it exists to-day were no more than that then outlined it would not merit the description which we are bound to assign it of a comprehensive system of colour photography answering the requirements of both the amateur worker and those who regard colour photography as a serious and commercial pursuit.

#### Manufacturing the Screen-Plates.

The basis of the process is a combination of the linear filter and emulsion, which the promoters name the "Florence Heliochromatic Screen Plate." As in the Lumière process, the filter is placed between the glass and the emulsion, but in fine lines. The method of producing this banded filter of the fineness of 1,000th to 1-1,000th of an inch constitutes the first step in advance of the Warner-Powrie process. Joly ruled his screen with a travelling pen; MacDonough did so, too, and also applied a band of colour from the ruled edge of a wheel. Mr. Powrie compares his by printing from a grating an image in bichromated

Warner-Powrie process is that, without in any way altering this preliminary operation, the colour negative or positive is available for:—

1. Preparing duplicates.
2. Preparing prints on paper.

Both of these developments are possible only with a screen plate with linear ruling, and both are carried out in the simplest manner conceivable by a method, indeed, which is so simple that it is hardly possible to suppose that it was not tried by early experimenters with the ruled filter-plates. It will help an understanding of this method if we first take No. 2 of the appendages mentioned above, and explain how a set of full-tone negatives is obtained from the line negative made in the first instance.

#### Three Negative from One.

The triple-line screen-negative in colours is placed in a printing frame with its filter side (i.e., the glass) towards a source of light from which parallel light falls upon it. The light passes through a filter which allows only light of one of the three colours of the screen plate to reach the printing frame. In contact with the film side of the plate is laid a sheet of glass (or celluloid or a metal frame), the thickness of which is chosen in relation to the distance of the frame from the light, and also to the angle through which the frame is subsequently turned during part of the exposure. On this glass again in the dark-room is placed a sensitive plate, and the whole set up in readi-

Fig. 1.

Fig. 2.

Fig. 3.

loid, which is converted into a transparent gelatine relief, is stained so as to form one series only of the three bands of the filter. A second series is printed after shifting the grating a determinate distance (the width of one line), and a second printing undertaken. The last and completing colour is obtained in the same way, and the method, which, from the description, appears more impracticable than others, has been found to be technically right, and to permit of the manufacture of screen glass of finer ruling than the 300 lines per inch which MacDonough failed in ruling on the manufacturing scale. After the application of a panchromatic emulsion, the "Florence Heliochromatic Plate" is ready for the production at one exposure of a negative in colour, or, if the negative image be reversed, of a direct positive transparency in colours. The above is a very sketchy outline of the system which has been worked out for the continuous production of the screen-plates by cheap and almost automatic means, and without the possibility of unruled or overlapping bands, but the description suffices to indicate the application of a photographic method to the manufacture.

#### Replicas in Colour on Glass and Paper.

Thus far we have a process of preparing colour transparencies which can be put in the hands of the amateur, and will enable him to produce results with no more difficulty than is involved in making a lantern-slide. But the essential feature of the

ness for exposure. One-third of the total exposure is given with the plate at right angles to the rays of light, one-third with the frame inclined towards the light to a certain extent, and one-third with the frame inclined away from the light to an equal but opposite degree. A moment's consideration will show that with a correct adjustment of the three factors of light distance, thickness of glass and angle of inclination, the set of bands occupying only one-third of the plate which are obtained at the first exposure, is duplicated on one side of the bands (first printed) on the second exposure being made, and on the other side of the first set of bands on the third exposure being made: with the result that a full-tone positive is obtained, representing the exposure through, let us say, the blue band. A similar series of exposure enables the same to be done in the case of the red and green sensations, with the result that the worker is in possession of a set of positives which he can use as he thinks fit in any process of three-colour printing.

The originators of the Warner-Powrie process admit that in this process of abolishing the linear formation a slight aberration is introduced, and is inseparable from the manipulation above described, but the amount of variation is found to be negligible in practical work.

#### Reproducing Screen-Plate Negatives.

We can now pass to explain what is actually of more importance to the maker of pictures in colours, namely, the printing of

the negative colour transparencies obtained at one exposure. The method is the same in principle as that just described for three positives, but instead of using three separate plates, one single panchromatic screen plate is used with the linear screen behind the glass, screen side in contact with it, and with its lines crossing those of the colour negative. There is no need to register the two screen plates. As before, the three exposures are given in the perpendicular and the two angled positions, the three stages of the operation being shown in figure 1, where A is the colour negative, B the plain glass, and C the sensitive screen plate on which the positive is impressed.

Fig. 4.

Showing how admixture with two-thirds black with one-third pure colour takes place in printing from a screen-plate positive on "Uto" paper.

Figure 1 shows the first printing at right angles: figures 2 and 3 those duplicating each band on either side of the first; as a result, the copy in colours is obtained of the ruling of the second plate only, and without the introduction of black or of white, which takes place if a copy be made from a negative or positive respectively in the ordinary way.

There are other ways in which this triplication of the negative images may be secured. By the use of mirrors (to multiply the light sources) at such distance from the frame and at suitable angles, the same effect is produced at one exposure as is obtained by shifting the position of the frame.

Three sources of light (incandescent, electric, or gas lights) will also accomplish the same result; or, by covering the window of the room, leaving three, four, or five inches in width and printing by daylight at a sufficient distance from the window, it

Fig. 5.

Showing how the full colour effect is obtained in printing on "Uto" paper from a Warner-Powrie screen-plate positive by aid of inclined mirrors.

is practicable to secure the necessary sharpness of the image and to eliminate the lines by juxtaposition.

It will be remembered that in the "Colour Supplement" to THE BRITISH JOURNAL OF PHOTOGRAPHY of July 5 Dr. Mees was the first to point out that the printing of a colour-screen positive from a negative (or positive) also on a screen-plate cannot be successfully done, for the reason that in the case of printing from a negative the positive copy is diluted with white and the colours all weakened, whilst in the case of making a positive from a positive the reverse occurs, viz., admixture with black: the colours in the copy being greatly degraded. This fact

was further confirmed by Dr. J. H. Smith in the "Colour Supplement" for August 2, in the case of the "Uto" bleach-out paper, but at the time both these writers were unaware of the method above described which Mr. Powrie employs to get rid of this drawback. Both have since expressed their admiration for the most simple solution of the problem in the case of the Warner-Powrie process. The great transparency of a Warner-Powrie colour print on glass is a good reason for assuming that the lantern lecturer will find in it alone of all the one-ply systems available or suggested the means of preparing slides which can be projected by lanterns of ordinary power.

#### How the Warner-Powrie Process Makes "Uto" Paper Usable.

The difficulty which under ordinary conditions attends the use of the "Uto" bleach-out paper for the copying of a positive transparency on a "Uto," an "Autochrome," or a Warner-Powrie screen-plate will be understood from Fig. 4, where the positive is represented one or two bands of red in the latter screen-plate. On exposure to light only those strips of the "Uto" paper under the red bands will become red, the adjoining bands of blue and green which in that part of a transparency representing a red object are opaque remain black on the "Uto" paper and consequently the region which shows the bright red consists of only one-third the brightest red the paper is capable

Fig. 6.

Diagrammatic view of the printing frame corresponding to Fig. 5, a and b mirrors inclined at about 110° to the surface of the positive.

and of two-thirds black. The difference between a linear plate and a grain plate in this respect is that in the case of the former there is a quick and easy way out of the difficulty, whereas with a grain colour-screen it is hard to imagine any way of escape. The method used in the Warner-Powrie process is explained by Fig. 5. A mirror is fixed to each side of the printing frame such an angle that the rays of light reflected from them triplicate the action on the paper by bringing into action a band right and left of that impressed on the "Uto" paper by direct light. In other words, the full colour possible by the paper is obtained without dilution with black. Fig. 6 is a rough drawing of the attachment actually used. It consists simply of two mirrors (a and b) inclined at an angle of about 110 deg. to the surface of the frame. The device, of course, greatly accelerates the printing of the paper, which, as anyone using it knows, is capable of great improvement in sensitiveness.

#### The Final Appeal—Results.

It would be easy to pooch-pooch the Warner-Powrie process and the claims of its promoters were unsubstantiated by results. In fact, the almost sensational character of certain of the methods would justify such a prejudiced frame of mind. But the proof of the pudding being in the eating, it is not possible to dismiss this development of the Florence Heliochromatic Plate lightly. It has been our privilege to examine a large collection of the screen-plates used in the process and a large number of the results. These latter consist of the original screen-plate negatives (in the colours complementary to those of the original

transparencies in colour printed from them by contact printing frame without any registration and having all the colours of the original, and sets of continuous tone colour-sensitised positives made from the original screen-plate negatives by the process which we have already described. The last, though not colour, and though differing in no visible way from ordinary positive transparency, were, to our thinking, the triumphant proof of the working quality of the Warner-Powrie process. To see a negative in colours which are dissolved throughout the plate in bands 1-600th of an inch in to the number of, say, 2,000, and side by side a set of positives representing the separation into three separate colours, the blue, the red, and the green in the subject, and all without a single effort to register, was, in our mind, an experience nearer allied to the stories of the days of magic than anything which we can recollect in connection with a "marvellous photography." Yet we handled more than one such set of positives prepared and arranged for the printing of a three-colour set by a subtractive process. The positive transparencies of the Warner-Powrie process differ from any we have seen in their great transparency. They are of so fine a ruling that the effect at about a foot from the eye is a continuous tone. Mr. Powrie, we believe, is right in preferring a fine ruling to any other of the same fineness for its quality of giving into a continuous tone, and though his earlier results of 100 to the inch are hardly coarse enough to attract attention to the structure, those on screen-plates of the finer ruling of 200 to the inch are as fine as can be wanted in prints or transparencies to be examined by the unaided eye. As to the pre-colour rendering we do not feel compelled to speak at length, for its perfection is a question of the adjustment of the filters

to the emulsion. We have been anxious to dwell in this article on the dispersal of the mechanical difficulties in the screen-plate process. Still, the inventors have convinced us of the thoroughly workable character of the method by the exquisite examples they have shown us of a great variety of subjects. Of late their endeavours have been in the direction of the maximum rapidity of emulsion, one specimen of which may be mentioned as an example of what may be expected of the process. It is a colour-screen plate positive of a man stooping over a flower-bed in a garden, and while it could not be claimed that the exposure had been sufficient, the picture is a triumph for an exposure which, as it itself shows, must have been at most one-fiftieth of a second.

#### Screen-Film Colour Photography.

It should also be mentioned that the process of preparing the screen-plates adopted in the Warner-Powrie process is equally applicable to celluloid films, which, in fact, from its facility of treatment in lengths, is more readily handled than a number of plates. The method of duplication above described is equally applicable to films, and it is possible, although we have no experimental data to warrant the assumption, that the great transparency of the Warner-Powrie positives will permit of the realisation of the ambition of not a few inventors, cinematography in colours. Into that, however, there is now no occasion to enter. The process as we have outlined it contains enough to feed the desire to make its more intimate acquaintance. We have not exhausted what there is to say of it, but any further account must be postponed to a forthcoming issue, as must also an article by Dr. Kenneth Mees on the Warner-Powrie method of overcoming the difficulty of duplicating screen-plate negatives and positives.

## THE LIPPMANN PROCESS.

The following is an abstract of a paper by Professor S. R. H. Lippmann, which appeared in the *Travaux du Laboratoire de Recherches Biologiques* of the University of Madrid. The author's researches on the structure of the heliochromes appear in our "Colour Supplement" for August and September. One of the most important points is to procure chemicals of the greatest purity and to see that all vessels used are chemically clean. A bad example of gelatine or inferior silver salt will cause impure whites or degraded colours. The gelatine sold by Lautenschlager, of Berlin, which was first recommended by Neuhauss, gives, the author thinks, more brilliant results than Drescher's. The silver nitrate and potassium bromide used were Merck's, and marked "Purissim pro analyse." The formula is as follows:—

Gelatine .....	62 grs. ...	4 gms.
Distilled water .....	3½ ozs. ...	100 ccs.
Potassium bromide .....	8.5 grs. ...	0.55 gms.

For summer the quantity of gelatine may be with advantage increased by 0.5 or 0.7 gms. (7.7 or 15.4 grs.).

The above should be placed in a glass beaker and heated in a water bath, with constant stirring, until the mixture attains a temperature of between 95 and 105 deg. Fahr. Then the sensitizers should be added:—

Cyanine, 1:500 alc. sol. ....	84 minims ...	5 ccs.
Erythrosine, 1:500 sol. ....	34 minims ...	2 ccs.
Glycin red, sat. sol. in abs. alc. ...	135 minims ...	8 ccs.

The glycin red solution must be prepared only about an hour before use, as it rapidly precipitates.

Immediately after the addition of the above, the silver nitrate should be added all at once:—

Silver nitrate freshly powdered	11.5 grs. ...	0.75 gms.
---------------------------------	---------------	-----------

The temperature of the emulsion may now vary between 77 and

105 deg. Fahr., but it is better to adhere to between 85 and 95 deg. Fahr.

#### A Point of Importance.

If a very fine grain is desired, the emulsion should be gently stirred whilst the silver bromide is being formed; if, on the other hand, a more rapid emulsion is required, it is advisable to mix the emulsion in a bottle and shake it well. The author's experiences have proved that sensitiveness is to a great extent dependent on the physical phenomenon of agitation. The speed of emulsions can thus be made to vary between 1 and 3. It is also possible to increase the speed by digesting the emulsion for half an hour at 105 deg.

Emulsification will be completed in 3 or 4 minutes, and the mass should be filtered through two thicknesses of filter paper. Enough should be poured on the glass to flow easily over it, and the excess should be drained off. The plates should then be placed on a levelling slab to set. It is advisable to cover them at this point with a cardboard box-lid, or something to prevent dust settling on the film. When it has once set this need not be feared.

The plates may be washed in running water for ten minutes, or merely left in water for an hour and the water changed three times. It is very advisable, as suggested by M. Lippmann, to immerse the plates before washing for a few seconds in absolute alcohol. This removes the air bells, and allows the washing-water to have access to the film.

Too much stress, the author thinks, has been laid on the temperature at which the plates should be dried. Neuhauss states that it is impossible to obtain the colours if the plates are dried under 77 deg. Fahr., but at this temperature the gelatine will melt, and the film almost invariably frills. The author has found that except for a slight increase in speed

in plates dried at 68 deg. in two hours, there is no difference in colour-rendering when they take twenty-four hours to dry.

Considerable stress has also been laid on the thickness of the film, but the author has obtained excellent results on films varying in thickness from 5 to 40  $\mu$ .

#### Aids to Speed of Emulsion.

The most satisfactory emulsions are unfortunately considerably slower than wet collodion. It is possible to increase the speed by raising the temperature of the emulsion to 105° deg. Fahr. The same result can be obtained by adding a drop or two of ammonia to the emulsion; the addition of sodium sulphite proposed by Valenta is also efficacious. All these increase the speed of the emulsion by increasing the size of the grain of the silver halide. The best emulsions—that is, those that give the most brilliant whites and colours—are the slowest. The speed of the plates can be increased by immersing before use in

Acetic acid .....	5 drops	... 5 drops
Absolute alcohol .....	3½ ozs.	... 100 ccs.
Silver nitrate, 10 p.c. sol.....	25 minims	... 1.5 ccm.

This solution must be quite clear when used, and the plates must be exposed within an hour of bathing in this.

It may be taken as a general axiom that it is not advisable to use this or any other speed increaser unless absolutely essential. The silver bath just mentioned has a great tendency to produce metallic fog, though the use of a perfectly clear solution and perfectly pure mercury will get over this trouble.

#### The Filter Developer and Intensification.

It is necessary to use a filter in front of the lens—preferably a cell containing a weak solution of erythrosine and aniline

yellow or potassium bichromate. Any excess of blue and rays makes it impossible to obtain clear whites. On the other hand, when working in the afternoon, when the blue and rays are more or less reduced in intensity, the screen may be dispensed with. It is impossible to give any idea of the effect of the exposure, as the factors are numerous and so varied.

Development should be effected by immersing the plate in

Water .....	8½ ozs.	... 250 ccm.
Pyro (1.25 p.c. sol.) .....	170 minims	... 10 ccm.
Potass. bromide (10 p.c. sol.)	203 minims	... 12 ccm.
Ammonia .....	50 minims	... 3 ccm.

After ten or twelve seconds the plate should be removed and well washed. It is useless trying to obtain the necessary intensification by development alone. Prolonged development merely causes fog in the interspaces between the laminae.

After washing, the plate should be immersed in mercuric chloride solution till it is quite white, then washed for five or eight minutes under a tap, and then re-developed in

Sodium sulphite .....	1½ ozs.	... 50 ccm.
Amidol .....	1 teaspoonful	... 1 teaspoonful

This will keep for two or three days. The plate should always be washed, and then dried.

It is not advisable to fix the plate, as this alters the distribution of the silver between the laminae. There is no fear of any blackening of the silver halide, as a plate exposed for eight days to sunlight suffers no change in colour or transparency.

The finished picture should be mounted with Canada balsam in contact with a low-angle prism, or it may be examined in a tank of benzol. The back should be covered with asphaltum or better still, a solution of gum dammar in xylol and printed ink.

## THE PHOTOGRAPHIC SALON—A FIRST IMPRESSION

THE Press-day of the Linked-Ring Exhibition allows us just time to peep into the Salon and run home to get an anticipatory paragraph into our current week's issue. Obviously, criticism worth the name is not possible; but a forceful impression is probably better gained by such a hasty method than by any other. And this is ours. The gallery, even with half-a-dozen journalistic prowlers in it, appears crowded. Spaciousness has been sacrificed to furniture and garden-stuff. The walls are lined with something that might be named grass-wicker, if the term were not too elegant for the purpose. We understand that a professional "decorator" has been pressed into service: hence the result has the conglomerate appearance that comes of too many brilliant ideas, and it suggests at once a Munich picture-gallery, a Continental restaurant, and a packing-shop of a furniture manufactory. There seems to be no reason why, upon the closing day, the committee should not stand by to rip the packing material off the walls and wrap up the purchasers' pictures in it. The buyer of Mr. Rawlins's twelve-guinea work might be favoured with an extra outside piece of the brown variety from the dado; but, joking apart, this stuff carries the old "Lessian" idea too far. We are not sticklers for precise neatness, but the

joints and rough-and-ready appearance of this stuff are not to be overlooked. It should also be mentioned that the loose particles from it cloud the air affect the nasal membranes and induce the symptoms of hay-fever. The velarium is also too fussy, being pieced and patterned, and these embellishments appear irritating to all the glasses to the great damage of the pictures. By having an extremely low the velarium has a depressing and stuffy effect spite of its blow-holes.

The show as a whole is again not a great one. Several members have made creditable efforts to send fine things, and among these the works of Mr. Arbuthnot and Mr. Horsley Hinton are not the least remarkable. Dührkoop is great in his "Convention," but some of his other works do not stand out. A fine view of Harlech will reinstate Mr. George Davison's reputation in the minds of many. Two American ternerities bearing the name of Cavendish Morton are full of that rare quality "style." Other Americans are less than scarce. There is Coburn, no Steichen, no Stieglitz; but as against this credit to the Linked Ring make a special point of a selection made in Paris by the French Committee. Many of these are presumably oil-prints; but the selection is of varying merit.

"LONDON" is the title of a compact and handy guide for the use of the visitor to the metropolis, which contains much useful information in a comparatively small space. It gives a list of the chief places of interest in and around London, accompanied by brief descriptive notes, together with information as to the various exhibitions, art galleries, places of amusement, hotels, etc., the latter

portion of the book being devoted to the more picturesque suburban resorts and the facilities they afford to the sportsman and naturalist. This little volume, which may be obtained for the small sum of 1s. 6d. is published by the proprietor, Mr. J. W. Cundall, at 8 and Essex Street, Strand, W.C., and by Messrs. Greening and Limited, 91, St. Martin's Lane, London, W.C.

## THE COLOUR OF URANIUM-TONED IMAGES.

June, 1906, a discussion took place in this paper on the subject of uranium toning, and Mr. E. J. Wall kindly sent some plates that had been exposed in an H. and D. machine for further experiments. The point of the discussion referred to was the colour obtained by varying the proportions of the solution. The following experiment was tried with Mr. Wall's test, using strong solutions, as I had before fairly well determined the possibilities of weak solutions that are quickly exhausted. A plate was cut into two strips, and No. 1 was immersed in a solution containing 4 grs. of uranium nitrate and 8 grs. of potassium ferricyanide per ounce, while No. 2 was treated with a solution containing 8 grs. of uranium and 4 grs. ferricyanide per ounce. The strips were immersed simultaneously, and were both examined in about two or three minutes. No. 1, in the bath containing an excess of ferricyanide, was then distinctly redder than No. 2. They were placed in the baths and left for an hour, at the end of which time the two strips were apparently the same colour in the highest densities, while No. 2 was faintly redder than No. 1 in the lower densities. The colours in the low densities were thus reversed in the course of an hour. The difference between the two colours was at no time very striking. No further brown was produced. The two colours were brownish, one being slightly browner than the other. It does not appear to me that the assumed existence of two ferrocyanides of different colours will account altogether for these results. The most rational explanation seems to be a different rate of action and a different rate of exhaustion. Some toned prints that I made long ago, and recently submitted to the Editors of this journal and to Mr. Wall, show distinctly that true brown (even sepia) tones can be obtained by slight toning conducted with weak solutions that are quickly exhausted, while red tones are normally obtained when a sufficiently concentrated solution is allowed to act for some time. In the case of these recent experiments the solution containing the maximum amount of ferricyanide may be expected to act more rapidly than the other, and therefore in a given short time to produce a redder tone. In a longer time we might reasonably expect both

images to be equally affected and of the same tone, provided neither solution has become exhausted. This appears to have been the case in the higher densities. The reversal of the tone in the lower densities is a curious feature, and does not apparently accord with either Atterburg's theory or with the one I feel most disposed to believe in. The difference is, however, very slight; so slight that I should not like to say too positively that it is confined to the lower tones. If it really exists throughout the tones the explanation appears to be simple, for we may most reasonably assume that the solution containing the excess of uranium retained its power of action for a longer time, and so carried on the toning in No. 2 to a slightly further and redder stage than in No. 1. In this case solution No. 1 must have become exhausted, or nearly so. It is impossible to say whether this was so or not, but both solutions showed signs of decomposition long before the time was up, and as a matter of fact several of the first experiments failed from this cause. Finally, I had to conduct the operations practically in the dark to avoid this decomposition, and even then the plates were badly stained.

These experiments are thus inconclusive, but they have not tended to confirm Atterburg's theory in my opinion, while they do seem to me to be in accord with my own idea that the slight variations produced by different formulæ are due mainly to different speeds of action. I may add that strip No. 2 shows a more matt surface than the other in all tones, which seems to suggest that the solution applied to it retained its power longer. The gelatine is badly stained in both strips, especially No. 2, and there is obviously some reaction between the gelatine and the solutions. This is the case in many photographic operations, and when it is so we may reasonably suspect that the reactions produced in the image are different from those that would occur in a test tube. I do not know if the Atterburg theory depends on test-tube experiments or not, but it seems highly probable, for the difficulty of analysing the results (which difficulty must have been considerable) would not have been lessened by the presence of the gelatine.

C. WELBORNE PIPER.

## A BUSINESS SYSTEM FOR PHOTOGRAPHERS.

[The following address on the employment of the card index in the photographic portrait business re-asserts the advantages of that method, which were pointed out in the paper by Mr. Pirie MacDonald in our issue of August 16. Yet the subject is of such pre-eminent importance in a photographic establishment that the professional may be advised to make further acquaintance with it in the notes by Mr. G. W. Harris, which we take from "The Photographer's" report of a recent convention in Dayton, U.S.A.—Eds. "B.J."]

Our best business men say that "the only way to learn to do a thing is to really do it." Everyone knows that if you are told, or shown, how to do a thing, it will not stamp itself on your memory; yet if you do it yourself it not only forces itself upon your brain, but it stays there, and it immediately forms a basis for further improvement, no matter how small the point it may be; for when we gain a good idea it grows and advances us in practical experience. The photographers, at their annual meetings and exchange of ideas, have raised their purpose and have made a plan of "give and take" of photographic knowledge that has helped every one of us. We know that no one can know it all, and that each of us can make a beneficial trade by giving his knowledge and experience for that of another; for while he gives the knowledge to one man, and that without loss of anything to himself, he is handed back plans and thoughts of others.

I had been asked by our president to give a paper on any subject, and had decided on "System in Plan of Business" (see "B.J.," August 16, p. 615), and found that the President of the New York Society at that convention was giving a part of the idea I had intended giving here. It was so well received that it strengthened in me the belief that the idea was a good one; hence I give the plan and system of our studio in Washington.

Of course, there are parts in this system which may not fit in your business, while others may see good in the part you reject. If I give some of you a good idea to think about, I am well repaid. I have made a sketch of the main features that I wish to call your attention to.

The features are, first, the ledger card, where you find the name, the address, the number, the order, the cash paid, the date, and when promised; second, the sitting slip, that tells

the operator the sitter's name, the size wanted, the date, the number of plates exposed and how many are good; third, the proof that the original order is written on; fourth, the proof sack, that holds the proof and that gives the name, the address number, the order, the date the photographs are promised, and what disposition to make of the work when finished, and the date of delivery.

The best way for me to tell you my story is to take a customer in our studio. When Mr. Jno. Doe comes in for a sitting we do not try to sell him photographs; and let me explain

The Ledger Card (reduced in depth).

right here that I find I must talk a little about business, which I will avoid as much as possible while explaining our system; but we show him sizes and styles until the reception lady finds out what he wants, then, taking him to her desk, she writes the ledger card in this manner:—

Mr. Jno. Doe.

No. 8, John Street, New York City ..... 1,000  
after which it is placed in a card cabinet case marked "Sittings," where it stays until the order is given. We also at this time make out this sitting slip, which goes to the operator; the name, the number, the size, the date slip, giving the whole cue to the operator without any further instructions of the reception lady. He then proceeds with

The Sitting Slip.

the sitting, and when through marks the number of plates he used in each size. This slip is placed on one exposed plate, and when the holders are changed the number is placed on one plate. The sitting slip goes to the typewriter, who makes as many stickers as there are plates numbered on the slip. The stickers are all made on gummed paper, and have the number and name on them. The next morning these stickers and plates go back to the operator, and he cuts them apart and fastens one on each negative. The negatives are then

counted and the total of good ones are marked on the sitting slips. The slips are then filed away by number for future reference. Of course, the proofs are made as usual, the negatives being filed away by the number, the proofs going to the customer. When the proofs are returned, then is the

The Printing on Proof Sack.

and then the card is placed in the order box, where it left until paid.

The proof is now placed in an envelope, the face of which is like this: The number and order goes in the corner, name and address in the middle, and the date in the upper left-hand corner, the word left to read that tells what

with it when the order is completed. This order-envelope, with the proof inside, then goes with the negative to the retoucher, who notices the proofs for correction and changes hair, dress, etc.; then to the printer, who need not ask any questions, for the whole instructions are on the proofs. When it goes to the finisher, who sees readily what mount they are on and how to trim. They are then sent to the receptionist for delivery. She looks up the card in the order book and places on the envelope the amount of order, cash paid, and total due. Then she notifies the customer by postal card at all is ready, or delivering the work as per her customer's instructions if to be mailed or sent by express, as it is shown on the face of the proof sack. On the lower line of proof sack she notes when and to whom she delivers the work. The transaction closed, the proof sack is filed by number, and waits a duplicate order, and the card is filed by letter, if account is paid in full, where it also rests until a duplicate comes in.

Now the points that I wish to call to your particular attention are, that this whole system is so arranged that nothing is forgotten, not even to the promised date, and that no questions need be asked by any one of the help, for such department has its own complete instructions. First, the sitting slip. We use this that the operator may know at all times who the sitter may be, that the number of the order is always before him for the marking of the plates. By the way, this serial number is placed on the sitting slip when the proofs are printed for us. For the line it gives you on knowing how many plates the operator uses and how many failures he had, which is a good rule to follow, even if you do your own operating.

The ledger card. This is where you control your whole business, for in the card system you have, first, your sitting card, where you place all the cards that show you the sittings you have made, and as they stay in this box until photographs are ordered, you always know in at least a few minutes to have not ordered, and if you use a good "follow up" system you can readily find out why your sitters do not order, and by using a little time once each month you can keep your box fairly clear, and you readily find out why your customers are not pleased with proofs. Next, the order box. You never place a card in this order box without first putting an order on it, and you never leave a card in this box when it has been paid in full, for the paid cards go into boxes marked "Closed," etc. Hence you know that all the open accounts, or all money due you, is in this box, and when the first of the month comes you are not running back through a ledger or register book, passing over numerous closed or paid accounts, to find your money due you, but there they are, every card showing money, money, money. You cannot miss an account, nor is it too much trouble to write your bills when the first comes. It is all packed in a nutshell, so speak, easy to handle and easy to control.

The reason of our not taking an order when the sitter comes, unless, of course, it is an out-of-town customer, is that we found people continually changing their order when they saw the proofs; second, that we make the proofs the original order, and it is written on the back of each proof as the order is given. This system allows none to say: "I did not order this, etc."; and, third, the printers and finishers can make no mistake, for each proof is marked plainly how many each, what paper to use, the size and kind of mount, while on the face of the proof the retoucher looks for all changes that are to be made.

We use the envelope to hold the proof, for delivery, instructions, when, how, and to whom delivered, and for filing away by number, so that when the duplicates are desired we get the proof for second order, that no mistake is made in finishing from the wrong negative.

We make all proofs on 5 by 7 paper, therefore we use the regular 5½ by 7½ cheap manilla envelope. We find that it is much more convenient than other sizes, for we use this same kind of envelope for accepted negatives.

Experience has taught us that the best card to use is the regular Yawman and Erbe stock 4 by 6 ledger card, as we find that it is sufficiently large to hold all orders, and yet not too big for easy handling. It also has the advantage of keeping both money columns together, and, being a stock card, there is no extra printing expense.

I have tried to give you all the main points of our system, and I hope I have made it plain to all.

G. W. HARRIS.

#### FORTHCOMING EXHIBITIONS.

- September 13 to October 26.—Photographic Salon. Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.
- September 19 to October 26.—Royal Photographic Society. Sec., J. McIntosh, New Gallery, 121, Regent Street, London, W.
- September 30 to October 25.—Society of Colour Photographers. Sec., Henry J. Comley, Surrey House, Stroud, Glos.
- October 5 to 12.—Bristol Photographic Club. Entries close September 23. Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.
- October 10 to 12.—Dumfries and Maxwelltown Photographic Association. Sec., T. Armstrong, 41, Moffat Road, Dumfries, N.B.
- October 16 to 19.—Rotherham Photographic Society. Entries close October 7. Sec., H. C. Hemingway, Tooker Road, Rotherham.
- October 17 to 26.—Edinburgh and Midlothian Industrial Exhibition (Photographic Section). Sec., A. T. Hutchinson, 15, Leith Street, Edinburgh.
- October 30 and 31.—Watford Camera Club. Sec., W. R. Gunton, 139, High Street, Watford, Herts.
- November 5 to 27.—West of England Industrial Exhibition (Photographic Section). Entries close October 5. Sec., A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.
- November 6 to 8.—Bedford Camera Club. Entries close October 31. Sec., P. C. Penny, 64, Harpur Street, Bedford.

THE "RAJAR" CAMERA, offered monthly by Rajar, Limited, of Moberley, Cheshire, for the best print on "Rajar" P.O.P. has been awarded to L. T. Hibbert, of Matlock, his entry having been judged the best received during August. The paper on which the print was made was purchased from W. Pilkington, Dale Road, Matlock.

THE ROTARY PHOTOGRAPHIC COMPANY'S employees held their annual sports in the grounds of their social club at West Drayton on August 31. There were all kinds of athletic competitions, including some suitable for the lady members of the staff. There was much keen, but friendly, rivalry between the offices and works contingents which kept matters in full swing till about 7 p.m., after which the prizes were distributed. Dancing on the lawn followed, the proceedings terminating with a concert and dance in the large hall.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between August 26 and 31:—

**CAMERAS.**—No. 19,108. Improvements in reversing backs of photographic cameras. Herbert Holmes, Albert Edwards, and Houghtons Ltd., 88, High Holborn, London.

**SHUTTERS.**—No. 19,177. Improvements in shutters for photographic cameras. Jules Richard, 53, Chancery Lane, London.

**PRINTING FRAMES.**—No. 19,220. Improvements in photographic printing frames. John Wilkinson and Alfred Wilkinson, 3, Brown Street, Market Street, Manchester.

**LIGHTING APPARATUS.**—No. 19,333. Portable lighting apparatus for indoor photography. Joseph Leclerc, 8, Quality Court, Chancery Lane, London.

**TRIPOD HEAD.**—No. 19,391. Improved stand-head for easily fixing and loosening cameras. Gustave Geiger, 68, Alterwall, Hamburg, Germany.

**FILMS.**—No. 19,433. Improved means of carrying and protecting photographic films. Fred Taylor Fletcher, Imperial Chambers, Albert Street, Derby.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SCREEN COLOUR PLATES.**—No. 194, 1907. The invention consists in the production of a screen plate for colour photography at one exposure, the screen being formed by lines in oil or greasy paint of one or more colours, which are applied by a ruling machine or by printing, the spaces left being filled up by dyeing the whole plate in a liquid which does not act upon the oil or greasy impression. On a sheet of glass, celluloid, etc., covered with a material which is permeable to water, such as gelatine, there is spread a coloured varnish, such as green for example, which is impermeable to water. Then, by means of a plane or circular ruling machine, there are drawn small parallel bands or tracks which are separated by intervals equal to their width. Then the sheet thus prepared is dipped for a few seconds into a water-colour, such as orange-red, for example, which impregnates the gelatine throughout where it has been exposed, leaving unacted upon the parts covered with varnish and only dyeing superficially the layer of gelatine.

The surface being cleaned, one will have a screen composed of green and orange-red bands which are arranged exactly by the side of each other and capable of producing by the two-colour process, beautifully coloured photographs.

A third colour will be distributed as follows:—

There is spread over a surface provided with two series of bands or lines, a second varnish which is impermeable to water, is colourless, and is designed to serve solely as a protector; one then produces fresh tracks which are a little deeper than those above referred to, in such a manner as to expose the lower layer of gelatine which the first bath did not have time to reach. These tracks will intersect the first-mentioned ones either perpendicularly or obliquely, and should be separated by spaces equal to twice their own width. The sheet will be then dipped for a few seconds into a blue-violet water-colour bath and a three-colour screen will be produced.

One may also take a transparent sheet covered with a thick layer of gelatine which is superficially coloured green, for example, on which is spread a varnish impermeable to water. After having drawn the first series of bands or tracks, the sheet is dipped into a second water-colour bath, then a colourless protective varnish is spread thereon, the second deeper series of bands or tracks is drawn, and finally the sheet is dipped into a third water-colour bath.

Also celluloid which is superficially coloured green, may be employed; this is covered with colourless gelatine and the first

series of bands or tracks is drawn sufficiently deeply for them to expose the colourless celluloid. The sheet is then coloured with a pigment dissolved in acetone, amyl acetate, or any other liquid which will bite on or penetrate the celluloid. There is then spread over the whole surface a second layer of gelatine, then the second deeper series of bands or tracks is drawn, and finally there is spread over the whole surface a third colour having base of acetone or amyl acetate.

The gelatine having protected the parts of the surface not acted upon by the chisel or tool of the ruling machine, and, after having freed the celluloid from the gelatine, there will be produced a screen which is capable of resisting water and a large number of other liquids.

As a third modification, the material employed is again celluloid. It is covered with a thin layer of gelatine which is coloured by means of a water-colour, then the first series of bands or tracks is drawn through the gelatine; the sheet is coloured with a second colour having amyl acetate or acetone for its base, which only acts on the exposed parts of the celluloid; the whole is then covered with a second layer of colourless gelatine; the second series of bands or tracks, which are deeper than the former ones, is drawn, and a third colour of the same nature as the second is spread over the sheet.

In all the above cases, the first series of bands or tracks can be drawn in such a manner that the interval which separates them shall be equal to twice their width. Then, after soaking and varnishing, similar bands or tracks are drawn extending nearly to the middle of the space which is afterwards soaked in the third colour. In this manner the screen is formed solely by bands which are parallel to each other; but this process has the disadvantage of only overcoming part of the difficulties of registration, whilst the method in which the lines cross over comes them entirely.

Thus, the second series of bands or tracks can be hollowed out to the same extent as the first; in this case, two colours are superposed at the point at which the series of lines cross each other and will form small squares which are black or have a dark colour and which have no other disadvantage than that of rendering somewhat darker the general appearance of the screen.

As a fourth modification, instead of forming the lines direct on the surface which it is desired to convert into a screen, the transfer method can be employed, that is to say, the lines are drawn by means of the machine on a hard accurately planed material, such as copper, zinc, lithographic stone, etc. Afterwards the parts in relief are coated, or the hollows thus formed are covered with a greasy colouring material, such as printing ink, and, by means of pressure, the series of lines is reproduced on a sheet of gelatine, for example. After drying, one can by the same means make a tracing of another colour crossing the first, then the bare intervals are coloured by floating the sheet on to a colour dissolved in water, to which the greasy colour will be impermeable.

In most cases, the gelatine may be replaced by collodion or by any other material which may be easily spread in a thin layer and is capable of absorbing colours having water, alcohol, etc. as their bases.

Also, in order to produce filmlike screens, one can use a circular ruling machine, which consists of a movable cylinder around which the sheet is rolled and of a chisel or cutting tool which is fed along by a leading screw and toothed wheels, the pinion is attached to the shaft of the cylinder.

In use, the screen produced by one of the methods described above, is covered with an emulsion which is sensitive to colour; and is placed in the plate- or film-carrier or frame of any suitable photographic apparatus, the emulsion being turned towards the inner face of the said carrier or frame in such a manner that the rays of light pass through the screen before reaching the said emulsion. A view will be taken in the ordinary manner and developed, then the negative so obtained will be converted into a positive, and after fixing one will have a photograph having all the natural colours. At the same time, one can employ the following process when it appears to be more advantageous by reason of its permitting the production of a large number of prints:—

Instead of spreading the emulsion on the screen itself, the

is placed in the carrier or frame, in the ordinary manner, a sensitised plate to which the screen is applied by putting the coloured surface of the latter against the emulsion on the plate. The view is taken, then the plate is developed after having been separated from the screen. The selectively acted-upon negative thus produced, when fixed, will enable an indefinite number of black positives to be obtained which, when suitably placed against similar screens, will immediately exhibit by transmitted light all colorations of the model. Theoretically this adaptation or fitting of the screen to the positive should be made in such a manner that each of the small coloured figures should coincide with the point of the image which it has selected, but since these thousands of figures or devices are similar to each other, are of equal dimensions and are symmetrically distributed over the whole surface of the screen, by reason of the regularity of the work done by the ruling machine, the registration may easily take place in an infinite number of positions.

The transparent support of the improved screens serving for the selection may be coloured slightly yellow so as to moderate the activity of the blue-violet rays.

The successive crossing of the two series of lines thus avoids the complications of registration in the manufacture of the screens. Moreover, the successive soakings each time exactly filling up the spaces produced, it follows that all the small colour-compartments are automatically juxtaposed without any space being left between them, a condition which is especially advantageous in the production of phototypes in which the selective effect is produced by light-filtration. The perfect regularity of the screens enables them to be applied to any positive produced by a similar screen, and consequently to enable the prints to be multiplied indefinitely. Louis Ducos du Hauron and Raymond de Bercegol, 17, Avenue Pauline, Joinville le Pont (Seine), France.

**ELECTRIC ARC LAMPS.**—No. 9,574, 1907. This invention relates to electric arc illuminating apparatus, which comprises a number of arc lamps enclosed in a single casing. Illuminating apparatus of this type is already known, but the constructions have the disadvantage that the carbon pairs are placed parallel side by side, so that the arcs produced by each pair are too close together; consequently the distribution of light is not satisfactory for the purpose required.

In the present invention this disadvantage is removed by

placing the carbon pairs, and consequently the arcs, at different levels and at comparatively large distances apart, so as to secure a favourable distribution of light and good lighting effects for photographic purposes.

A construction embodying the invention is illustrated in the

annexed drawing. Three carbon pairs are provided, for producing three arcs. The carbons are carried by pivoted lever arms all arranged in the same vertical plane. The two central arms *a* carry at each end *b* a carbon, and the lateral arms *c* carry carbons at their ends *d*. The carbons carried by the arms *c* are in alignment with the carbons at the upper ends of the adjacent arms *a*, and the carbons at the lower ends of the arms *a* are in alignment with each other. The arcs are struck and regulated by actuating the arms *a* by means of worm and toothed gear *f*, *g*, *h*, *i* arranged at the rear of the case. The worm *g* at the upper end of the spindle *f* meshes with two pinions *h*, which it rotates in opposite directions. Each of these pinions meshes with a toothed segment *i* fixed outside the case to the pivot or axle *e* of one of the arms *a*, so that the arcs can be struck and regulated by actuating the spindle *f* by means of the handle *f*<sup>1</sup>. The arms *c* are at the same time actuated by means of rods *k* which connect their ends *d* to the lower ends *b* of the arms *a*. The arrangement may also be so made that the worm and toothed gear only directly actuate one of the arms, movement being communicated to all the other arms by means of connecting rods.

An indefinite number of additional arms and connecting rods may be provided for carrying and controlling additional carbons, the connections being so made that all the arms can be controlled by means of a single regulating device. The provision of a plurality of carbon pairs enables the apparatus to be used with different voltages, since the lamps can be connected in series or in parallel.

As has already been mentioned, the arrangement of the arcs at different levels causes the light to be very effectively distributed, and the distribution may be improved by covering the inclined walls of the case *h* with ribbed or corrugated mirrors and by placing frosted glass or gauze screens in front of the lamps. Jean Schmidt, 70, Bleichstrasse, Frankfurt-on-the-Main, Germany.

## New Trade Names.

**IMPREGNITE.**—No. 293,709. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. Standard Varnish Works (a corporation organised under the laws of the United States of America), 23, 24, and 25, Billiter Street, London, E.C., manufacturers June 12, 1907.

**ACIFIX.**—No. 294,316. Photographic Chemicals. John J. Griffin and Sons, Ltd., corner of Kemble Street and Kean Street, Kingsway, London, W.C., photographic apparatus manufacturers. July 4, 1907.

**THE CINEMATOGRAPH IN GERMANY.**—The Kaiser (according to the "Tribune's" correspondent) has lately displayed great interest in the progressive development of cinematographic displays. Instruments for obtaining pictures of the recent fleet manoeuvres were conveyed by the Emperor's orders, both on the flagship "Deutschland" and on the Royal yacht "Hohenzollern." Similarly elaborate arrangements were made for recording the autumn parade on the Tempelhofer Feld last week. These series of pictures will be produced before the Kaiser at the Castle of Wilhelmshöhe at the close of the autumn manoeuvres. The development of cinematographic displays, especially in Berlin, is altogether remarkable. Cinematograph theatres appear to spring up like mushrooms all over the city, and to do good business. Recently school authorities and others have begun to raise a protest against these exhibitions, owing to their supposed deleterious effect on the minds of the children who frequent them. It is pointed out that these shows are often attended by crowds of children until late at night. Moreover, despite the severe censorship, it is declared that the scenes are frequently quite unsuited for children. It is urged that the cinematograph, instead of being left to such exploitation, should be much more utilised than is the case at present for educational purposes. It seems probable that a movement in such a direction will have emphatic Imperial support.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Pigment Prints from Bromides in 30 minutes by the Oil Process.

Mr. C. Welborne Piper, writing in the "Photographic News," gives the following instructions for an amended and more rapid process of preparing a pigment print direct from a bromide:—

Soak the dried print in water until limp, then bleach it in the following freshly mixed solution:—

Ozobrome stock solution .....	4 parts.
10 per cent. potash alum solution .....	4 parts.
10 per cent. citric acid solution .....	1 part.
Water, to make .....	20 parts.

When bleached, rinse very briefly under the tap, or dip into a dish of plain water to remove surplus bleaching solution, and then immerse in:

Sulphuric acid .....	1 part.
Water, to .....	20 parts.

Leave in this acid solution until the brown bichromated image has disappeared, and only a faint whitish image is left. If in a hurry use several acid baths in succession, until the bath ceases to be stained yellow, otherwise leave the print to soak for about twenty minutes.

Next rinse print well under the tap and immerse it in the following fixing bath to remove the silver bromide image that is left:—

Hypo .....	4 ozs.
Sulphite of soda .....	1 oz.
Water, to .....	20 ozs.

Fixing is very rapid, two or three minutes being ample. After fixing wash the print and pigment. Time in washing can be saved if the print is simply floated face down on the hypo solution. Fifteen minutes' washing will then be enough. If the print is soaked in the hypo half an hour's washing should be sufficient, as minute traces of hypo left in the print are of no consequence. After washing it is well to pigment at once, but if more convenient the print can be dried and pigmented later. Ten to twenty minutes' soaking will be enough before pigmenting. It should be noted that, though the print will pigment very readily after the acid bath and before fixing, yet the fixing is necessary, otherwise the silver image left will rapidly darken on exposure to light. The ultimate image left is a very faint yellow or yellow-green. It is almost invisible, and is quite unaffected by light, at any rate so far as the colour is concerned. When the acid bath has acted there is fairly strong relief in the print, enough to be felt when the finger is passed over the surface of the image.

### Brushes for the Rawlins Oil-Printing Process.

So much depends upon the condition of the brushes (says Mr. G. E. H. Rawlins in "The Amateur Photographer") that it pays well to take care of them. Although they last a long time, they naturally deteriorate with use, and the washing "takes it out of them," even more than hopping and dabbing. It is therefore advisable to avoid washing them if possible. My plan is to wash my hands instead of my brushes! I keep two or three old brushes for the heavy pigmenting and rough preliminary work, and these I wash as usual after use. To distinguish them from the rest, I have stained their handles black. Their condition is not very vital, as they are never wanted for fine work, so washing does not affect them much. But for the gentle hopping work I keep all my best brushes, and as they never become heavily loaded with pigment I find careful rubbing on an old print, and then on the palm of my hand, generally cleans them quite enough to make washing only an occasional necessity.

### A Dust-proof Drying-Box for Lantern Slides or Negatives.

Every photographer (says a writer in "Focus") who has ever made a lantern slide has experienced the difficulty of drying his picture free from dust. Several expensive contrivances with gauze panels are on the market to accomplish this end, but the following arrangement will be found to be much superior to any of them. Purchase an ounce of dry granular calcium chloride at a chemist's; it will cost a penny. Place this in a small tin—one of those pressed-out tobacco

tins is the best, that is, one that is not soldered together, but stamped out of one piece of metal. Remove the lid, so that the drying agent is free to do its work, and place it inside the ordinary grooved lantern slide box. The newly-washed slides are then placed in the box, the lid closed, and in a few hours it will be found that the calcium chloride has extracted all the moisture from the films. The salt will in due time become fluid, owing to its absorption of moisture. All that is necessary to restore it is to take out the box and heat it on a gas stove or over the fire, until its contents are again solid and dry. The reason for the choice of a seamless box is now apparent. If the lid of the slide box does not fit tightly, it may be made airtight by gluing pieces of thin rubber around it, so that the rubber comes between the lid and the box. The hinges will yield a little and allow of the box being closed, notwithstanding the packing. If rubber sheeting is not available, pieces of blotting-paper will serve almost as well. A similar device could, of course, be constructed for use with a negative drying-box, although such is hardly necessary for negatives.

## New Books.

"How to Ensure Correct Exposure." By A. Horsley Hinton. 4d.  
 "Home Portraiture Made Easy." By A. Horsley Hinton. 4d.

In these "Little Books" from the office of "The Amateur Photographer," Mr. Hinton engages in what, we believe, an evangelistic preacher would describe as a "heart to heart talk." That is to say the moral pill is coated heavily with sugar, only in Mr. Hinton's case the medicine is technical, but administered with an abundant flow of explanatory notes, which nevertheless do not stray from the point in process of being impressed upon the youthful seeker after photographic guidance. The titles of the two booklets sufficiently describe their contents. In each case the reading matter runs to sixty-four pages, and the illustrations to a number of examples which do actually give a pretty good idea of mistakes which a beginner can make. The books are avowedly intended for photographic light reading; to be quickly scanned and their hints as quickly applied to difficulties into which the amateur has fallen. Such a purpose the admirably fulfil, and we can recommend that a pile of them be placed on a dealer's counter as a ready means of vicarious answer, at 4d. time, to a beginner who is in trouble with the two very common difficulties of photography, calculating exposure and arranging a "at home" portrait. Nos. 1 and 2 of the same series, we should add deal with "Development Made Easy," and "How to Make Bad Negatives into Good."

WE HAVE RECEIVED from the Scientific Shop (Albert B. Porter 324, Dearborn Street, Chicago, a series of circulars relating to the Ives replica gratings and spectroscopes. A reproduction, very much enlarged, is given of the test lines which are used for determining the quality of the gratings. The reproduction is about 6 in. long, therefore the complete spectrum would be no less than 18 in. With regard to this illustration the circular states that much detail has, of course, been lost in reproduction, but the line midway between E and b at wave length 5,227, is shown clearly resolved into a triplet. In testing the gratings all are rejected which do not resolve this line in the second order spectrum. As the lines are about twenty times as far apart as the adjacent lines in this triplet, it will be seen that these replicas have a resolving power in the second order spectrum twenty times as great as that needed to resolve the D line and ten times that required to show the nickel line between the D's. This is the guaranteed minimum resolving power of the smallest of these gratings. To secure full advantage of this resolving power it is, of course, necessary to use good slit, a high eyepiece, and to focus the image of the sun on the slit. It will be noted that the second order spectrum is used, but still this is a very good test, and speaks well for the quality of the gratings, though personally we should prefer the Nickel line between the D's in the first order, which is that generally used in practice.

## New Materials.

"Isostigmat" (Anastigmatic) Lens. Made by R. and J. Beck, Ltd., 68, Cornhill, London, E.C.

We have received an example of this lens for test and review. It was very fully described some months ago in Messrs. Beck's paper, read at the R.P.S., and reproduced in this journal, it is necessary to go into the details of its construction. The lens submitted to us is No. 4, Series II., of 6 inches focal length and apertures 8 to  $f/22$ , and is recommended for use on a  $5 \times 4$  plate. At full aperture it covers a half-plate with very fine definition. Tested on a small source of light the visible aberration is as small as we have seen with any other anastigmat; very much smaller than is often the case with more expensive lenses of high quality. The field also seems to be remarkably flat. The single back combination at  $f/11$  covers the half-plate very satisfactorily. The single front combination seems to be not quite so good, but is quite serviceable. We did not detect any flare image, though one can be readily found if the lens is reversed. Apparently, the non-symmetrical construction does not cause flare. There is no doubt that this is an extremely good lens, and it is remarkably cheap at the list prices. The low price is due to the fact that the lenses are uncentred, and all of power, with flat curvatures that are easily worked. There is no sacrifice of cheapness in the performance of the lens, though we suggest that it might very well be sent out in a somewhat cleaner condition as regards the interior. The mount is very small and light, and is well suited for a light hand-camera. As the lens has been on the market for a considerable time and many photographers have tried it, it is unnecessary to say much about it. But those who have not tried it can be assured that it is remarkably good value for the money. The prices in magnalium mounts are only £2 12s. 6d. for a 4.5-inch lens at  $f/5.8$ , Series II., and £1 17s. 6d. for a similar at  $f/7.7$ , belonging to Series III. These prices compare very well with those for modern "aplanats" or R.R. lenses.

Gold Chromium Intensifiers. Made by Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C.

Just as is the number of compounds at the photographer's disposal for the intensification of negatives, there is still no single one which is in itself all the qualities which constitute a reagent, the ideal for a given purpose. Nevertheless, the chromium intensifier, which owes its recent re-introduction and improvement to the efforts of Messrs. Douglas Carnegie and C. Welborne Piper, possesses certain important and valuable features, which give it a high place among the intensifiers which can be used with confidence. In the first place, the results are of unquestioned permanence; in the second place, the process can be applied within a few minutes of the negative being out of the fixing bath; in the third the action is completed at every application of the process; and, lastly, the process is repeated to give any desired degree of intensification without staining or otherwise impairing the negative. The formulae and directions for the use of the intensifier, as Messrs. Carnegie and Piper recommend it, were the subject of an article by the latter in our columns not long ago, so that it is not necessary for us to recapitulate them. We may, however, give the procedure recommended by Messrs. Burroughs, Wellcome, and Co., which is as follows:—Dissolve one 'tabloid' in each two ounces of water, immerse the film, or print in this solution, gently rocking the dish, until the image is bleached to a buff tint. Wash under the tap until yellow disappears (10 to 30 minutes). Then re-develop fully with any 're-developer'. If greater density is required, repeat the process. One application will give sufficient increase of density, except in the case of very weak originals. When it is necessary to repeat the operation, the 'tabloid' is the best for re-development.

Our own trials of the 'tabloid' preparation have satisfied us of the stability of the intensifier in this convenient form. In place of the old, which we usually prefer to use as the re-developer, but had in hand, we employed rodinal, about 1:20, which gives a fine image on treatment of the buff coloured image produced in chromate bath.

We should like to draw special attention to the chromium intensifier for the improvement of lantern slides and bromide prints. Any

transparency which is to be subjected to great heat, as a lantern slide may, is best intensified by a method which does not involve the volatile mercury compounds. Uranium is unsuitable, on account of the toning action, and we are therefore forced to fall back on acid-silver, which was the best intensifier for lantern slides until the chromium process was worked out by Messrs. Carnegie and Piper. Despite the care and extreme cleanliness necessary, we may still use acid-silver for giving exceptional vigour to a lantern slide, but the chromium solution gives us all the power we need in ninety-nine cases out of one hundred. For bromides the chromium solution is even more useful than for lantern slides, since it gives just a slight intensification, with, at the same time, a change of colour to a beautiful slightly warm black, which is an immense improvement on the developed tone. We advise any one who has not tried the experiment to make a few bromides just on the under-side of full strength, and to submit a few of them to the chromium intensifier. They will be greatly surprised with the result, and for this and any other purpose we can recommend Messrs. Burroughs Wellcome's preparation, which is sold in 1s. bottles, holding enough for 50 oz. (usable several times) of bleaching bath.

## CATALOGUES AND TRADE NOTICES.

A CATALOGUE of the lenses of Planbel and Co., Frankfurt-on-Main, reaches us from this firm. It gives full particulars of the several series of anastigmat objectives sold as "Orthar," and obtainable at as large an aperture as  $f/4.5$ . The firm also issues telephoto attachments, among which is a lens, the "Tele-Peconar," which is placed on the front of an ordinary hand-camera objective to give a telephoto of various magnifications. The "Tele-Peconar," which appears to resemble the Dallmeyer "Adon," can also be used alone. It is sold of aperture  $f/9$  and  $f/5$ , at prices ranging from £2 to £2 14s. Messrs. Planbel's list contains many admirable examples of the use of these and other of their lenses.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, SEPTEMBER 14.

Hull Photographic Society. Excursion to Bolton Abbey.  
Uddington Amateur Camera Club. Outing to Lanark and Falls of Clyde.  
Chelsea and District Photographic Society. Outing to Greenwich.  
North Middlesex Photographic Society. Excursion to Sutton.  
North London Photographic Society. Outing to Sewardstone.  
Manchester Amateur Photographic Society. Outing to Thames Embankment.  
West London Photographic Society. Outing to Hoylelake.  
West London Photographic Society. Outing to Richmond.

#### SUNDAY, SEPTEMBER 15.

United Stereoscopic Society. Last Day of Entries, Landscape Competition.

#### MONDAY, SEPTEMBER 16.

South London Photographic Society. "Lantern Slide Making." John A. Hodges, F.R.P.S. Monthly Competition—(Lantern Slides).

#### TUESDAY, SEPTEMBER 17.

Royal Photographic Society. Annual Exhibition. Press View.  
Hackney Photographic Society. Presidents' Outing Lantern Slides. Lantern Lecture by F. W. Gosling.  
Blairgowrie and District Photographic Association. Lantern Slides. J. B. MacLachlan.

#### WEDNESDAY, SEPTEMBER 18.

Royal Photographic Society. Annual Exhibition. Private View and Soirée.  
North Middlesex Photographic Society. Lantern Slides. G. E. Williams.  
North Suburban Photographic Society. Print Competition.  
Evertown Camera Club. Ten Minutes Papers.

#### THURSDAY, SEPTEMBER 19.

Royal Photographic Society. Annual Exhibition Opens.  
London and Provincial Photographic Association. "Theory and Practice of Time Development." W. K. Slater.  
North London Photographic Society. "The Oil Printing Process." A. W. Green.  
Handsworth Photographic Society. "Lantern Slide Making by Reduction." A. E. Teague.

JANDUS PHOTOGRAPHIC LAMP.—Messrs. Drake and Gorham, Limited, advise us that by an oversight the price-lists recently sent out had no notification of the 10 per cent. advance which they were compelled to put in operation some little time ago on account of the continued rise in the cost of raw material, which advance is still in force.

## Commercial & Legal Intelligence.

**CHARGE OF EMBEZZLEMENT.**—At the Birmingham Police Court, on September 3, William Henry Evans, 36, of The Brooklands, Albert Road, Stechford, a Birmingham cashier, was charged with embezzling certain sums of money belonging to his employers, Messrs. Hurman, photographic apparatus dealers, of Victoria Square. Mr. Adcock appeared on behalf of defendant. Detective Inspector Goldrick explained that the prisoner was charged with embezzling £16 0s. 3d. on July 16 and £6 on July 20. He understood that the prosecuting firm did not wish to deal harshly with the prisoner, and would like the case settled that morning. It was agreed to take only the charge relating to the £16, and to this the prisoner pleaded guilty.

Mr. Arthur Webb, manager to the prosecuting firm, said that the prisoner had been employed by them since April, 1906. He received the money in question from one of the assistants, and failed to enter it in the cash book or to account for it. Replying to Mr. Adcock, witness said the firm did not know that the prisoner was actually carrying on other businesses on his own behalf. He had had transactions with the firm, but not to the extent of £200 worth of goods. There was some money still owing on the account, but the firm would say nothing about that.

Mr. Adcock said that it was an exceedingly sad case. The prisoner had a young wife and four children. He commenced to work for Messrs. Hurman at 40s. a week salary. A friend was interested in the photographic line, and prisoner was foolishly persuaded to go into the business. He had instructed him to say that he had spent £200 with the prosecutors since he started. He was not trying to justify his position, but if he had not been interested in these businesses he would not have been where he was to-day. The concerns had not prospered, and the money had evidently been expended in them. He had done his best to dispose of the businesses, and if he had done so certain moneys would have been paid to Messrs. Hurman.

Replying to the Deputy Stipendiary, Mr. Webb said that the total defalcations amounted to a little over £100, there being thirty different items. He did not think prisoner had been living above his means, he seemed to be a very careful and hard-working man.

Inspector Goldrick said that prisoner had explained to him that the businesses, which were at Coventry and Ashted Row, Birmingham, had been a great worry to him. The defalcations extended over ten or twelve months. There was nothing wrong before he embarked on this venture.

The Deputy Stipendiary said there were certain extenuating circumstances in the case, and prisoner was sentenced to four months' imprisonment.

**THE RIGHT TO SEE FIXED STARS.**—Sheriff Campbell Smith, Dundee, on Tuesday issued an interlocutor "recalling and quashing" a deliverance by Dundee Town Council authorising the erection of an overhead bridge across Westfield Avenue by Valentine and Sons, Ltd., photographers.

The appellants were Dundee Tramway and Carriage Company, Ltd., and their contentions were that the Town Council have only rights over the street, so far as is necessary for its use as a highway or for the purposes of laying under it pipes, drains, or sewers, and that nothing can be erected above the street without the consent of those owning or having a right of access along the solum of the avenue. They further contended that the Council acted illegally in delegating to the Burgh Engineer the power to approve of the overhead bridge proposed to be erected by the Messrs. Valentine in so far as regards its design, size, and construction.

The Town Council were called as respondents in the appeal, and subsequently Messrs. Valentine were also cited as respondents.

Both respondents pleaded that the appeal was incompetent, and the appellant's averments were irrelevant. The Town Council further pleaded that their approval of the plans and sections submitted to them was expressly sanctioned by statute, and that for almost forty years the Police Commissioners and Town Council had dealt with the applications for the erection of gangways over streets, and either approved or disapproved thereof.

Messrs. Valentine and Sons pleaded that the proposed gangway was in the public interest, and lessened the traffic in Westfield Avenue, and that such gangways were common in the cities and

towns of Scotland, and that having obtained statutory authority erect the bridge the appellants had no right to interfere therewith.

In a note to his interlocutor, the Sheriff says he has looked at plans and other papers also by the naked and assisted eye at Westfield Avenue itself. He has the impression that the money value of the question between the present pugilistic litigants cannot, in present state and complexion of the locality, be a large sum. He formed, however, a clear opinion that the appellants, be they many or few, whose property abuts on this lane, and who have an unputable right-of-way through it, have the right to see the fixed stars from any part of it free from all artificial obstructions that have not become unchangeable by the lapse of forty years.

The magistrates and Town Council, he continues, are the trustees for the citizens of Dundee, and have the right to manage the property of the corporate inhabitants with the same care, intelligence, integrity and circumspection that they manage their own property. The magistrates of Dundee are also the judges in the Burgh Court, under Charles II.'s charter, and pretty much in accord with it under the Common Law of Scotland, which grew to be applicable to burghs, the power of feudal lords grew weak. Town Councils may manage and throw away at less than its value the property of the inhabitants, and after forty years' acquiescence or silence the generation of citizens may have no redress, as was made terribly apparent in the great Dundee stipend case of fifty years ago. Before the civil law of the country as a litigant a Town Council stands on the same platform as any other litigant, the individual litigant being, in the eye of the law, not distinguishable in quality, however petty in quantity, from the corporate litigant, however large the census may be.

Police Acts, written many of them under the inspiration of a love of power, have in them concealed by their verbosity many quibbles, provisions, comments the Sheriff, but it may be said broadly that as a rule, these queer provisions must be construed in the light of indisputable general law of the country. They can never be strained to warrant interference with private property, except on some plausible pretext of tax-gathering, necessary for the obtaining of money for general advantage of the community.

**THEFT BY A PHOTOGRAPHER.**—William Weare, of 4, Tickle Street, Wigan, appeared at the Wigan Borough Police Court, on September 3, on a charge of being drunk and disorderly. He admitted it. Chief Constable said there were circumstances in that case which made the charge against the prisoner that day simply trivial compared with the one that might follow. He was a tramping photographer taking photographs of shop fronts and so forth. A few weeks ago he went to Pemberton to two young men who had just started the business there, and submitted what appeared to them—and it appeared to be honest—some flowery testimonials, on the strength of which they "took him on." They lent him a camera to go and get orders for photographing shop fronts, small parties, etc., he disposed of the camera, which was worth £5 or £6. Then he went and got some things—plates, films, etc.—from Mr. Phillip, the name of his employers. Two charges might be taken against him, one of disposing of the camera, and another of obtaining goods by false pretences. The camera had been recovered, and it depended upon what the magistrates did with the prisoner that morning whether or not the other charges would be preferred against him.

The Magistrates' Clerk: Have you a complete answer to the charge, Prisoner: Yes.

The Chief Constable: All right; if the prosecution is gone on with I am prepared to prove the case.

The magistrates, without regard to the other alleged offences, fined Weare 2s. 6d. and costs.

**MIDLOTHIAN PHOTOGRAPHIC ASSOCIATION.**—This association has been recently formed in Edinburgh for the promotion of artistic and scientific photography, and several names of well-known photographic workers are amongst its members of council. Spacious lecture committee rooms have been secured at 5, St. Andrew Street, where lectures, demonstrations, discussions, and meetings for social intercourse are held at least twice during each month. Those in the neighbourhood interested in photography who may be desirous of joining such an association would do well to communicate with the hon. secretary, Mr. Robert Oliver, 6, Murieston Terrace, Edinburgh, who will be pleased to supply any information.

## News and Notes.

**THE BRISTOL PHOTOGRAPHIC CLUB'S COMMITTEE** have decided to buy as many as possible of the pictures gaining awards at their exhibition next month, with the double object of encouraging competitors and forming the nucleus of an interesting permanent club collection. The committee have also arranged that the judge—Mr. F. M. Sutcliffe—shall give two whole days to the judging, as they feel strongly that this important matter requires more time than is usually allowed for it.

**REFLEX-CAMERA PHOTOGRAPHS.**—The Kodak Company announce the opening of an interesting exhibition at their gallery, 115, Oxford Street, W. There are on view a number of remarkable instantaneous photographs made with the "Graflex" camera. Among these photographs is an extraordinary one of a horse throwing a somersault, the horse being snapshotted completely in the air wrong way up. The exhibition also includes some very ingenious and artistic articles for wall decoration and furniture, in which enlargements on Kodak Royal Bromide paper have been utilised. These have been specially designed to demonstrate the possibilities of Kodak photography applied to home decoration. The exhibition opens on September 12.

**GRIMSEY AND DISTRICT CAMERA CLUB.**—The annual general meeting of the above club took place on September 4. There was a good muster of the members, Mr. A. H. Hewitt being in the chair. A report and balance-sheet, covering the period elapsed since the formation of the society and showing a balance in hand, was placed before the meeting, and was considered highly satisfactory. The following were elected officers for the ensuing year: President, Mr. P. W. Riggall, J.P.; vice-presidents, Dr. G. A. Grierson and Messrs. A. H. Hewitt, W. A. Vignoles, and S. E. Ward; treasurer, Mr. J. N. Benson; council, Messrs. W. J. Brumpton, G. H. Glover, V. W. Green, F. W. Healey, H. Johnson, L. Towle, and F. Poisey; secretary, Mr. H. S. Ogley, 17, Edward Street; portfolio secretary, Mr. W. B. Johnson, 46, Ainslie Street. The question of a photographic exhibition was discussed, and the council were requested to draw up a scheme and report to a future meeting. Votes of thanks to the officers for their services during the past year brought the meeting to a close.

**SOLUBILITIES IN GLYCERIN.**—M. Ossendowski ("C.R. Soc. Chim. class."), using redistilled glycerin obtained by the saponification of tallow, has obtained the following solubility factors. One hundred parts of glycerin (by weight) at 60-62deg. F. dissolve:—

Ammonium carbonate .....	20.00	Sodium bicarbonate .....	8.06
Ammonium chloride .....	20.06	Calcium sulphate .....	5.17
Barium chloride .....	9.73	Copper acetate .....	10.0
Borax .....	60.00	Copper sulphate .....	36.30
Boric acid .....	11.0	Tannin .....	48.83
Benzoic acid .....	10.21	Mercuric chloride .....	8.00
Bismuth .....	2.0	Zinc chloride .....	49.87
Potassium arsenate .....	50.13	Zinc iodide .....	39.78
Potassium iodide .....	39.72	Zinc sulphate .....	35.18
Potassium cyanide .....	31.84	Sulphur .....	0.14
Potassium chloride .....	3.72	Phosphorus .....	0.25
Potassium chlorate .....	3.54	Oxalic acid .....	15.10
Sodium carbonate .....	98.3	Quinine .....	0.47
Sodium arsenate .....	50.0		

**PHOTOGRAPHING CYCLISTS.**—A writer in "Cycling," of September 4, the course of an interesting article on the best way to produce realistic photograph of a cyclist on his machine, recommends the following methods, the results of which are represented by half-tone reproductions of some very satisfactory photographs:—"The method supporting the cyclist needs consideration. That usually adopted at the spur of the moment is the placing of a brick under the lowermost pedal, or resting the same on the kerb, and the result, whatever may be as regards the cyclist, is always a splendid portrait of the brick, which stands out most obtrusively, instead of suppressing itself, as we hoped it would do. I think it almost hopeless to adopt this plan when a broadside-on view is wanted, but if the rider is content with three-quarter one, the task is quite easy. Some part of the machine

or the rider can nearly always be arranged to hide the support, and our first illustration shows how successfully this may be done. I defy anyone to detect the method of support, which was a brick placed under the right pedal. Of course, a stable-yard is not the sort of place in which a cyclist would be likely to ride about at large, and in this respect the picture gives itself away. Also, if it had been taken in sunlight, the shadow of the brick would probably have been very pronounced. But it shows well enough what can be done in the way of rendering the artificial nature of the support unnoticeable. Undoubtedly the most satisfactory plan, however, is to support the cyclist by a length of stout cord, tied at one end to the saddle pillar and at the other to a fence-pole or a strong hedge-stake. This is the plan I have adopted more than once, and always with success. The cord should be long, so that the cyclist may be well away from the hedge or fence—the further away the more complete is the illusion, and the less suspicion is there of the fence serving as a support. If the cord is tied to the top of the saddle pillar, just at the clip, it will not show in the slightest, and, provided it is strong, the rider can adopt any position which may be considered most suitable, without fear of losing his balance. I suggest that the side photographed should always be the right, as the outside of the chain-wheel is generally more pictorial than the inside; and, in this case, the right foot should be forward and the top run of the chain stretched tight. If the machine has a free wheel, and a brake has to be held on to keep it motionless and preserve the tension on the chain, take care that the rider's hand is not in a strained position, the left hand being preferable for this purpose, as being further from the camera. Another way of getting over the movement difficulty is to follow the cyclist round with the camera, and to press the shutter release whilst so doing. This sounds like heresy to those amateurs who have always insisted on the necessity for holding the camera perfectly still during exposure, but it is a very good compromise method when the aim is to secure a sharp picture of the cyclist, irrespective of his surroundings. The cyclist is sharp, but the background of foliage runs into streaks on account of the movement of the camera. It is essential, if this is to be successful, that the rider should "freel" past the photographer, or his moving feet will certainly be blurred and indistinct.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—The committee of the above association have fixed October 10, 1907, as the final date for receiving papers in connection with the Henderson award for the current year. The award (which is open to the photographic world) is one of the value of £5, and may be either in cash, a gold medal, a silver or bronze medal, and part cash, or apparatus, as selected by the recipient of the award. It is made yearly for the best paper upon a photo-chemical or kindred subject, and short abstracts of any competing papers should be sent to the hon. secretary as early as possible. In connection with the above we may add that the L. and P.P.A. are making a very special effort to double their number, in order that the association shall become a monument to its founder (the late Mr. A. Henderson), who died on July 5 of this year. Visitors are ever welcome at the meetings, on Thursdays, at 8 p.m., at the White Swan, Tudor Street, E.C. and may always rely upon hearing some good discussion upon things photographic. The hon. secretary, Ernest Human, 43, Whitta Road, Manor Park, Essex, will gladly answer all inquiries in connection with the work of the L. and P.P.A. and the Henderson award.

**PHOTOGRAPHIC AND PROCESS INSTRUCTION IN MANCHESTER.**—The prospectus of the photographic and printing crafts department of the Manchester Municipal School of Technology—in itself a beautiful specimen of typography—should be of interest to every photographer residing within reach of the educational facilities of Manchester. For this department of the school it may justly be claimed that in no other institution in these islands and probably in none in Europe can an equally comprehensive course of instruction be obtained in the graphic arts, from the making of the original for an illustration to the binding of a printed volume. Manchester lays stress on the "course" as a factor in education, whether technical or classical, but its photographic department is nevertheless arranged to meet the requirements of those who wish for training in any one or two single branches of their art or craft. It is a regrettable feature of professional photography that many enter its ranks with scarcely more than a smattering of the technical knowledge essential to their work. If we could open the eyes of half the number who

thus "start in" without training the workrooms of the technical departments, such as that in Manchester directed by Mr. Charles W. Gamble, and in London by Mr. A. J. Newton, would be crowded. Yet all we can do is to emphasise once again the great importance of technical knowledge and the facilities which exist for obtaining it. The work of the photography department of the Manchester Municipal Technical School is divided into the following sections: (1) Pure photography; (2) photo-engraving and various photo-mechanical methods; (3) letterpress printing, including composing, reading, and machine and press work; (4) lithography, including drawing, design, and printing; (5) bookbinding, including design, forwarding, and finishing. The scheme of instruction in each section includes lectures and practical work, and courses are arranged in the different branches with the object of giving such preliminary training as will be useful to those who intend to enter the various industries coming under the different divisions. The subject of pure photography may be studied by those who wish to enter the business in its different branches, or who desire to devote themselves eventually to the photo-mechanical industry. In addition, a course is arranged of a more strictly technological character for those students who may desire to study more deeply the various processes and the fundamental principles upon which this branch of applied science depends. This course extends over a period of three years, and leads to a degree of the University of Manchester as one of the optional subjects in the division of applied chemistry in the faculty of technology. For such students who are unable to devote themselves through want of time or other circumstances to an extended course of study in photography or photo-mechanical processes special courses may be taken at the discretion of the director of the department on days and at hours and upon such terms and conditions as may be arranged. The department contains a complete photographic studio with three dark-rooms for general photographic work by daylight and by artificial light, and for the special purposes of photo-mechanical reproduction processes. The studio contains four cameras, on anti-vibration stands, designed for copying by reflected and transmitted light. They are arranged for half-tone reproduction, one of them having a number of additions designed for the specific purpose of demonstrating the principles of half tone screen negative-making. Three sets of arc lamps, one set of four, one pair of open type, and one pair of enclosed type, are arranged on overhead traversing gears by which all the necessary movements can be obtained. A studio camera and portable cameras are provided, as well as other cameras for special purposes. For copying plans and tracings there is a Hall cylindrical copying apparatus, fitted with an arc lamp, by means of which reproductions up to double-elephant size can be made. The three dark-rooms are arranged for wet collodion sensitising, wet collodion development, and for dry-plate and collodion-emulsion work. A complete optical equipment is provided, and all the necessary arrangements for the testing of photographic lenses. The studio is also provided with complete apparatus for various three-colour processes, prism and diffraction grating photo-spectroscopic apparatus, arrangements for the testing of sensitive surfaces, and for the determination of the speed of shutters. A room is fitted specially for the purpose of negative preparation and print-making by the various light-printing processes. The whole of the machinery is driven by electric motors. The lithographic and collotype machine-room is equipped with a combined lithographic and collotype machine, direct driven by electric motor, three hand lithographic presses, a collotype hand press, a copper-plate press, and a "Reliance" hand press for the proofing of process blocks. The lithographic drawing and design studio is supplied with all the appliances for the various kinds of work. The etching and collotype preparation room contains fittings of entirely new construction, and there is a complete equipment for the making of line and half-tone photo-engraved blocks, including three-colour work, and for photo-lithography and collotype. There is also a block-mounting and finishing room, with router, saw, bevellers, and all other tools required in the mounting and finishing of process blocks, electrotype and stereotype plates. The school session commences on September 16, 1907, and continues until July 17, 1908. There are vacations of two weeks at Christmas and one week each at Easter and Whitsuntide. Special attention should be drawn to the course of day lectures by Mr. Gamble on "The Practice of Photography," and to the evening courses in negative-making, portraiture,

silver, platinum, and carbon-printing, retouching, and photo-engraving in its various branches. The school provides great facilities for practical work in these subjects.

**CANVASSING FRAUDS IN LEEDS.**—We are glad to see the "Yorkshire Post" giving prominence to the following letter: "May I be allowed, through the medium of your paper, to warn householders of the methods adopted by certain persons who appear to be now canvassing the city? The modus operandi of these people is to call at the house at a time when the male members of the household are not likely to be at home, and to endeavour to interview the lady of the house. If successful, permission is asked to be allowed to make an enlargement of the portrait of some member of the family free of charge "just as an advertisement." No sensible person supposes that the caller is in the philanthropic line, but the request is not acceded to the lady expresses his great astonishment that Madam really means to say she won't have the enlargement given to her for nothing. The persistence of the man, and desire to get him out of the house, results in his being allowed to take away a portrait, the lady arguing that it can at least do no harm, and that she incurs no expense. In a day or two the man returns with the enlargement, and then introduces for the first time the question of a suitable frame, or which he has samples with him. First by peaceable means, but if these fail, then by adopting a bullying attitude, he more often than not succeeds in disposing of a frame at a price far in excess of that for which it could be obtained in the shops; the lady of the house being in the end only too glad to pay the price to be rid of her objectionable visitor. Let there should be any who imagine that the promise of a free enlargement will be fulfilled, I may add that one case came to my knowledge in which a lady declined to purchase a frame, whereupon her enlargement was destroyed before her eyes and the pieces thrown into the street. Ladies will avoid considerable anxiety and annoyance to themselves by declining to have any dealings with this class of person.—TOM TIT.

**LANCASTER PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held in the Friends' Hall from November 25 to 28—latest date for entries, November 16. Full particulars and entry forms may be obtained from the hon. secretary, Mr. Walter Gunson, "Manesty" Scotforth Road, Lancaster.

**THE SOUTHERN EXHIBITIONS.**—Again Southampton, Southsea, and Hove societies combine to hold their annual exhibitions in November and December. As before, one entry form and fee is sufficient for all three, and the exhibits are forwarded from exhibition to exhibition free of cost to exhibitors. There are two competitive classes, ten awards being placed at the discretion of the judges. There will also be an invitation section this year. Entry forms can now be obtained from S. G. Kimber, Oakdene, Highfield, Southampton. The dates of the three exhibitions are: Southampton—November 1 to 23; hon. secretary, S. G. Kimber, Oakdene, Highfield, Southampton. Southsea—November 28 to December 4; hon. secretary, Gilbert Wood, 10, Pelham Road, Southsea. Hove—December 11 to 14; hon. secretary, Stanley Road, 12, Old Steine, Brighton.

**PROFITABLE PHOTOGRAPHY.**—We look to our lay contemporaries for news of the things which are about to revolutionise photography—to make the fortune of the photographer, but it is rarely we light on such a really entertaining item as the following, from a newspaper in the Sister Isle:—"Some years ago a bright young girl was employed behind the counter of a London photographer's studio. It seemed that the art of photography had reached its climax; that there was nothing else to be done in the way of its advancement, except to invent a practicable method of reproducing colours. This observation a young woman was impressed by the boredom which posing entailed upon most of the customers. She set her nimble wits to work to devise some improved plan, to evolve an idea that was worth while. She did it. To day she owns one of the most successful photographic galleries in London, and is making her fortune rapidly. She simply makes a photograph of the face, then measures one limb, and from the basis produces a splendid, gracefully-posed portrait of the entire body without worrying the sitter to strike various tiresome attitudes. How does she do it? That is her secret—the profitable idea that sprang from her busy brain."

## Correspondence.

*Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*We do not undertake responsibility for the opinions expressed by our correspondents.*

### PENDULUM ROCKERS.

To the Editors.

Gentlemen,—In an article in your "Ex Cathedra" to-day you commend the use of a pendulum rocker for use in the dark room. I would wish to warn your readers that this pattern is not to be trusted as advertised in the price lists. No doubt, when the weight is very heavy, it will work for some time; but, as usually sold, it soon stops and requires constant attention. When rocked without oil, or with a dry one, it will appear to answer well, but if a few ounces of water be put into the dish it will be found that it very soon comes to a stand. The reason of this is that the water moves in the dish which follows the tilting of the dish; just as the dish is moved and begins to reverse its motion, the wave strikes the end of the dish and checks the motion. This action, repeated at each tilt, finally brings the whole to a stand. A heavy weight is inconvenient, and at best is but a palliative. The clockwork rockers are noisy, and I should think they are liable to injury from solutions being poured over, and, too, they are noisy.

An efficient rocker is still a desideratum. The pendulum as now on the market does not fill the rôle.—I am, Sirs, yours obediently,

J. F. TENNANT.

11, Clifton Gardens, Maida Hill, W.

### SKIN AFFECTIONS AND THE TONING BATH.

To the Editors.

Gentlemen,—I have read with interest the correspondence in the "Ex Cathedra" on above subject, as I have suffered for about twelve months with bad hands, but I notice that most of the correspondents attribute the trouble to the developer. My case is different. I never develop, I only tone (sodium gold and sulphocyanide bath). My symptoms are an itching and burning of the prints, afterwards the skin cracks just as if my hands were frost-bitten, the skin peels off my fingers, and the itching is almost unbearable. I tried a remedy you suggested a few weeks ago—boracic acid, glycerine, and lanoline—but to no purpose. I should be pleased to hear of a remedy for this.—Yours faithfully,

OAK SIDE.

Wentworth, W.

September 6, 1907.

### WATER AS A CAUSE OF BLISTERS IN BROMIDES.

To the Editors.

Gentlemen,—Re your remarks on blisters last week, let me tell you my experience last winter. I have always used the water from the tap near the door of my work-room, but just before Christmas the pump got out of order, and I used the town supply, with the result that I had blisters galore, big, little, and middling size. I, of course, blamed the makers, who said the paper was right, but I did suspect the water. When after a time I had the pump repaired the blisters disappeared like magic, and I have had no more since. The water was extremely "hard," the town supply very "soft." I use hard water for bromide paper whenever possible, and this trouble.

OTHELLO.

VERY BEAUTIFUL but little-known part of Surrey lying among the hills some 700ft. above the sea is to be described and illustrated in the next work which Messrs. Simpkin, Marshall, and Co. will issue. The course of a few days under the title, "On the Hills of Health, and the Week-end Cottage Dweller."

## Answers to Correspondents.

\*<sup>a</sup> All matters intended for the text portion of the JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*<sup>b</sup> Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*<sup>c</sup> Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\*<sup>d</sup> For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

E. R. Yerbury, 1, Hanover Street, Edinburgh. Two Photographs of the Band of the 2nd Bn. of the Seaforth Highlanders.

V. Andrews, 68, Chepstow Road, Newport, Monmouthshire. Photograph of Mr. F. Richards at his Easel.

F. Ormiston-Smith, 32, Devonshire Road, Forest Hill, London, S.E. Six Photographs of Rudolf Bernet, and Four of Christian Bohren.

C. Smy, 75, High Street, Upper Houghton, Dunstable. Photograph of an Old Print, Priory Church, Dunstable, in the year 1100.

PATENT QUERY.—We have brought out a stand to take two 7ft. vignetted continuous grounds, one on either side, on double rollers, which is very simple, effective, and up-to-date. Same is on castors, and easily moved about to any position. We write to ask you how we could get it protected cheaply till we could offer it to some of the large firms. Will you kindly give us any information you can? Of course, we do not want to go to the expense of a patent till we see if same would be likely to go, but we have no fear on that score.—L. B.

Provisional protection would cost you only £1, or about £2 2s. if you employ a patent agent to draw up the specification for you. You can obtain all the information in a circular, obtainable from the Comptroller of Patents, 25, Southampton Buildings, E.C.

STAINED NEGATIVE.—Would you kindly oblige by telling me how to clear some whole-plate negatives? I develop them in pyro-soda, weakened with water about three times the quantity. After developing and fixing they are very yellow, and I tried to clear them with nitric acid and water. It cleared them a little, but did not clear them perfectly. I took a bromide print off. The exposure was very long. After that I reduced the negatives with ferricyanide and hypo in the ordinary way, and cleared a little more with nitric acid. After that there was a milky appearance on the backs of the negatives, as if they were only half fixed, which made them take longer to print. Would you kindly tell me how to remove this and clear them up; also how to harden the film?—F. E. GRAY.

You have decomposed the hypo by the acid treatment, and the whitish appearance of the negatives is the result. We fear they are beyond recovery now. You may try re-fixing them for 10 minutes in a bath of say, 6oz. hypo per pint, but we doubt if that will clear away the sulphur deposited on the film. You should know that hypo and a strong acid such as nitric, hydrochloric, or sulphuric should never be allowed to act on each other in the film. The best way to harden the gelatin film is in 10 per cent. solution of alum or 10 per cent. formalin solution. We advise you to study a handbook of after-treatment, etc., such as "Finishing the Negative" (Dawbarn and Ward, 1s.).

E. T. BUSE.—W. H. Smith and Son, Strand, and Kingsway, London, W.C.

FLASHLIGHT POWDER.—Please give us directions for making one pound of the new flash powder mentioned in "B.J." for August 23, this is if it is not a patent. Can you say who sells cadmium nitrate free from acid? Also of what fineness does the magnesium powder require to be? Give address of a maker of magnesium powders?—T. H. BAKER.

We can give no further particulars beyond those contained in the article to which you refer. We personally have had no practical experience with any of the compounds mentioned. You will

see by our note on the subject that great risk is incurred in the making of any of the compounds by inexperienced persons. We should certainly not advise you to attempt to make any such quantity as a pound at a time. If you make any at all we suggest that you keep the ingredients separately, and then mix only sufficient for an exposure as required, mixing them on a sheet of paper, using a strip of thin cardboard as a spatula. Magnesium powder, suitable for the purpose, is sold by all the large photographic dealers. Nitrate of cadmium is supplied by such houses as Hopkin and Williams, Cross Street, Hutton Garden, E.C. They will doubtless supply it free from acid if requested. Flash powder is made by Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, E.C.

**LEAKY TAP.**—I have a large jar, containing stock solution of hypo, to which I have fitted a wooden tap. But the solution oozes through the wood and forms into crystals outside, which drop off. Is there any means of waterproofing the tap to prevent this? Your advice would greatly oblige.—CONSTANT READER.

It seems clear that you have not got a good tap, or it would not act as you say. We should advise you to get a good boxwood one. Failing that, you had better soak the hypo out of the one you have, thoroughly dry it, and then well rub in tallow or vaseline, so as to fill up the pores of the wood.

**TEST FOR HYPO.**—I should be extremely grateful if you would tell me through your columns what percentage permanganate should be mixed with water to tell whether the hypo is properly extracted from prints and plates after they have been washed.—F. W. DRAKE.

The test is simple. Add a few crystals of the permanganate to, say, a pint bottle of water so as to give it strong tint only. This may be kept as a stock solution. To test: Let a few drops of the water drain from the prints or negatives into a test tube, then add a drop or two of permanganate solution. If the colour is discharged you may know that hypo is still present. If the colour remains the whole of the hypo is removed.

**FADING PRINT.**—(1) Will you kindly tell me, if possible, the reason for this print (and others) fading? I always take every care to fix properly, and also wash all prints by hand, after fixing, in twelve changes, draining each print separately; they are dried as quickly as possible (spontaneously), and mounted by the dry-mounting process. This print has only been made about two months, and has been in the window for about three weeks, on and off. Would it be detrimental to prints if I used a stronger fixing bath than the one recommended with the paper, which is: Hypo, 1 oz.; water, 15 oz.? I should be grateful for any hints you can give me to ensure permanency of my work; the paper is C.C., and gives excellent results except for this. (2) Is there any book dealing with studio portraiture in colours? By this I mean real colour photography, and not hand-coloured portraits. If so, will you kindly give me the name of book and author, and say where I can get it?—C. C.

(1) We suspect that the cause lies in the treatment of the print, though in precisely what respect it is not easy to say from your description. It is the general experience that platinum toning alone gives results of less permanence than gold, followed by platinum, though a gold-toned print will not begin to go off, as a rule, until a year old. We advise you to adopt gold, followed by platinum, if you have not already done so. The numerous hints on C.C. paper on pages 786-9 of the current "Almanac" ought to assist you. (2) There is none. We should advise you to join the Society of Colour Photographers (secretary, Mr. Henry J. Comley, Surrey House, Stroud, Glos.), whereby you could come into communication with those willing to assist you personally.

**SHOWCASE RIGHTS.**—We should be much indebted to you if you would advise us on the following matter: We have recently opened a business at the above address, and for show purposes have placed in the front garden of the house a showcase. The case is the usual thing, about 11ft. long, 6ft. high, and 2ft. deep, standing on six wooden legs, sunk in ground. The case is back from the front railing 18 inches, and no part hangs over the footpath. A few doors above our premises (which is one of a row of private houses) shops have been erected, and the line of these shops, although in advance of the houses adjoining, is about 6 feet behind the line of the front palings of the houses. The case has been erected now about eight weeks. We have just received

a visit from the district surveyor, who says his attention has been called to our case, and that we must move it, as we have not got permission from the council to erect it, and that in any case it must not be advanced in front of the line of shops above, which would be some 7 feet back in garden, and that we must send sketch to the council and get permission to erect. We remember reading some time since in the "B.J." a case similar, in which a council went to law to compel the removal of a photographer's case, and to the best of our knowledge, lost. If you could advise us as to how we stand we should be extremely grateful, as to put back the case would be very detrimental to our business. STILLIARD AND CO.

Two summonses of a kind almost exactly similar to yours were brought last year, and were both lost. The first was that of Mr. H. Ernst, of 14, Finchley Road, N.W., who was summoned by the London County Council. The magistrate before whom he was heard described it as a piece of paltry interference which almost took his breath away. ("B.J.," January 19, 1906, p. 5.) The second case was that of Mr. W. P. Marsh, of Chichester, and was withdrawn on the magistrates holding that the showcase was not a building. ("B.J.," March 23, 1906, p. 235.) We advise you to acquaint a solicitor with these cases, and defend the summons.

**LENS QUERY.**—I have a lens (portrait) engraved T. Slater, London, which seems a remarkably good instrument, and with an unusual flat field, but not having heard the name, can you tell me if he was a maker or a dealer, and how long ago did he carry on business?—OTHELLO.

Slater was a maker of lenses, and his premises were situated in what is now the Euston Road. He was amongst the earliest English makers, and his lenses were in good repute at the time. He ceased, we think, to make photographic lenses somewhere about the early sixties.

**POSTCARDS.**—(1) Can you tell me if the pretty coloured postcard actresses are done with tints that we use to colour photographs, and how they are got so highly glazed, which I think must be done after tinting them? (2) I should also like to know how tinselling on them is put on, and where it can be obtained. I have a clouded background, which has become very creased, and whenever rolled up makes the marks worse on it. Can I do anything to it? I had thought of gluing some brown paper do the creases on the wrong side, but was afraid it would show through. I have had it taken off the roller and re-nailed on to try and do away with them.—B. D. G.

(1) Special aniline colours which dry glossy are sold by houses such as Fallowfield. (2) In tinselling, a little fixative or adhesive is painted on, and the jewelling powders dusted on. Reinemund and Co., New Zealand Avenue, Barbican, E.C., will give you prices of the materials and instructions for their use. If you glued paper on the back in the way you suggest, expect it would cause cockling of the background; in that case the remedy would be worse than the disease. We suggest that you lay the background, face downward, on the floor, and then go over the back of it with a wet sponge, making it evenly all over, and allow it to dry. This may, possibly, get rid of the creases. But if they are very pronounced it is doubtful if they can be successfully eradicated.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The first annual exhibition of the Society of Colour Photographers opens on September 30. (P. xviii.)

The Lumière Brothers receive a medal in the technical section the R.P.S. Exhibition for their invention of the "Autochrome" plates. (P. 705.)

"Autochrome" plates at the standard prices can now be obtained from Messrs. Adams and Co. (P. 711.)

A photo-micrograph, by Mr. J. H. Pledge, F.R.M.S., showing the black crosses "marking in the starch grain of the Lumière "Autochrome" plate, is reproduced on p. 721.

The frilling of "Autochrome" plates may be prevented by a procedure described by Mr. Welborne Piper on p. 711.

A recommendation of "The Amateur Photographer" is quoted on 717.

The Warner-Powrie Process.—Following some further notes on its latest development of screen-plate colour photography, Dr. Kenneth Mees points out the facilities of the Warner-Powrie system, the making of colour duplicates and prints on paper from the negative obtained at a single exposure in an ordinary camera.

Mr. E. J. Wall characterises the process as a most important advance. (P. 707.)

The Oil Process.—M. Puyo kindly specifies and illustrates the precise brushes used by him for the pigmenting operation in making prints. (P. 712.)

The R.P.S. Exhibition.—A brief impression of the exhibition as a whole appears on p. 712.

The Photographic Salon.—The first portion of a review of this year's exhibition occupies pp. 713-4.

## EX CATHEDRA.

### Honour for the Lumière Autochrome Plate.

It should be difficult to find a single dissentient from the award made in the technical section of the Royal Photographic Society's Exhibition to the Lumière Brothers for their "Autochrome" plate. If there is one, he cannot have seen the collection of three-colour transparencies on the plates which form a special section of the exhibition and constitute a chorus of encomiums more eloquent than any form of words. The invention has obtained and more than deserved a reception as enthusiastic as that accorded to the process of Daguerre, with which, in fact, it has a number of points in common. Its triumph is bound to fix attention for some time to come on the screen-plate methods of colour photography, more than one of which, if reports are true, are commercially imminent.

\* \* \*

### A Case for Protest.

A disgraceful scene, in which photographers figured, was witnessed on Saturday last on the Brooklands motor track and ended, according to reports, in a free fight. During the racing a car was overturned and two persons seriously injured. On their being removed to the office of the clerk of the course, a number (six or eight) of photographers—presumably Press photographers—endeavoured to push their way into the office with the idea of photographing the bruised and bleeding bodies under the hands of the medical men. This the officials prevented, and, seizing some of the most prominent amongst the photographers, hustled them away from the door, much to the satisfaction of the general body of onlookers. No doubt these men were employed by some of the newspapers which give illustrations of such sensational accidents as the above, and, it is to be hoped, pay well those who do their best to execute their commands. In the above case, had the photographers succeeded in their object, there is no doubt that some of the papers would have had illustrations of the injured and bleeding victims of the accident being treated by the doctors. It is, however, satisfactory to learn that the officials frustrated such an outrage on decency, for which the papers sanctioning such practices are as much to blame as the photographers.

\* \* \*

### Aluminium as a Reducer of Silver Chloride.

M. Emile Vigouroux, in a paper recently before the French Chemical Society, has described the results of some experiments on the use of aluminium as a reducing agent for the silver haloid salts. He has found that metallic aluminium is an active reducer of silver chloride in both acid and alkaline media, but as a practical

process recommends the treatment of the washed silver chloride when moistened with a little hydrochloric acid. Only enough of this latter is used to form a paste of the silver chloride, and the addition of fragments of aluminium then gives rise to a rapid reduction. The metallic silver thus obtained is found to have a high degree of purity, amounting to 99.5 to 99.6 per cent. of silver. The fact of the process requiring no accessories in the way of furnaces, fluxes, etc., specially fits it for the purposes of those desirous of recovering their own residues.

\* \* \*

**Sunday Photography.** Although there have been several convictions of late against photographers for carrying on their businesses on the Sabbath, Sunday photography is as largely carried on as it ever was, and is likely to be so long as the antiquated Act of Charles II. is the only one under which prosecutions can be taken. Last week a tobacconist and news vendor, Jacob Popp, of High Wycombe, answered the 300th summons against him for Sunday trading, in infringement of the Lord's Day Observance Act of Charles II. He was fined 2s. 6d. and costs. The utmost fine that can be inflicted, as we have said before, is 5s., and few photographers who carry on what is often a lucrative business on Sundays are likely to be deterred by such a penalty. It is noteworthy that it is only in country districts that this old Act is sometimes put into force, rarely in large towns. In some of them, such as manufacturing districts, a good amount of business is done, as many who want their portraits taken cannot afford the time to don their "Sunday best" on weekdays. To such, Sunday photography is certainly a great convenience, as without it their friends would be unable to possess their portraits. Still, the law does not look upon the taking of portraits, even in these circumstances, as a work of necessity such as to claim exemption under this ancient Act.

\* \* \*

#### **Cleaning Negatives.**

A correspondent last week asked for a method of cleaning a negative upon which sulphur had been deposited as the result of following a hypo bath with one of acid. The cause of the trouble was the attempt to remove pyro stain with nitric acid. The acid decomposed the hypo contained in the film, and thus the one trouble was supplemented by another. As a matter of fact, a simple acid bath is of little use as a remedy for pyro stain. This stain is not readily removed by any means, and if it is not wanted it should be avoided at the start by using a non-staining

formula. When it exists it can be reduced most effectively and safely by bleaching the negative in a solution of potassium bichromate and hydrochloric acid and redeveloping it with a non-staining developer. If sufficient acid is used there will only be very slight intensification and it will be found that the printing time of the negative is very much shortened. Good proportions are 10 grains bichromate and 20 minims hydrochloric acid in one ounce, while amidol is perhaps the best redeveloper. This process will also remove sulphur freshly deposited in the film from decomposed hypo, for the bleaching solution dissolves freshly precipitated sulphur somewhat readily. It may not do so if the sulphur has been in the film for some time, as in our correspondent's case, while this point is doubtful, the remedy is worth trying. The process is very safe and certain, and it seldom fails to materially improve a negative, though, of course, so stains are proof against it.

\* \* \*

#### **Copyright Pictures in National Collections.**

A case of some interest to photographers who copy pictures in public galleries came before the Vacation Court one week last week. From the report, it seems that the defendants in the case, Messrs. Clarke and Davis, being desirous of copying the picture of "Harmony," by F. Dicksee, R.A. (now on exhibition at the Tate Gallery) and of issuing the reproductions as postcards, obtained the permission of the Trustees of the Gallery to do so and proceeded with the work. Thereupon Messrs. Agnew and Sons applied for an interim injunction to restrain the defendants from infringing the copyright they held in the picture. When the case came on last week, the defendants said they were willing to submit to a perpetual injunction and the learned judge made an order to that effect. From this it will be seen that, although the Trustees of the Gallery had given permission for the picture to be copied, the reproducers were still liable to action for infringement of the copyright which existed in it. Several of the pictures in the Tate Gallery are still copyright, although the Trustees may give permission for them to be copied, that does not exempt the reproducer from proceedings under the Copyright Act if there be an existing copyright in them. That is a matter that the would-be reproducer should ascertain for himself before applying for the consent of the Trustees, or he may find himself landed in legal proceedings. Artists sometimes sell the copyright in their works and the pictures separately, in which case the owner of a picture has not the right to reproduce it.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

SCREEN-PLATE THREE-COLOUR PROCESSES and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

## TITLES FOR PHOTOGRAPHS.\*

year or two ago the "Studio" office published a book purporting to be for artists and photographers. It is a collection of poetical titles intended for pictures. Our contemporaries took it upon itself to empty its scorn upon painters for the mere idea of it, presumably for the sin of their having had for them a thing which they did not want, had asked for, and would never use. We wonder if that paper will change its point of view in its work, or whether it will, in consistency, ban photographers for humbugging cheats because this is prepared for them.

Without a doubt such a book embodies a ridiculous or it is manifestly one thing to be reminded of a line of poetry by some scene or its presentment, its another to look up a book of verses and couplets would a directory or a time-table. Suppose, for example, Harry gets a nice view of bathers on Ramsgate will he improve matters by looking out a title which thinks worthy of it, such, for instance, as:—

"The moving waters at their priest-like task,  
Of pure ablution round earth's human shores"  
"High-falutin' titles pall. Fancy the catalogue of a whose library owned a well-thumbed copy of this book! What an anthology of snips and snails it is! Nine times out of ten a plain prose descriptive cannot be beaten. Tags of poetry are a nuisance as is usually the case, they but put bald statements of fact into jingle or inversion. Where a poetic of service is in the case of an idea in a picture not be described in matter-of-fact prose, but which line of poetry will delicately direct and attune the . The sort of thing we are given a choice of here sunset on a summer's day," "The evening shades " "The evening twilight fades away," "The sun the fields." If the not extraordinary effects these jewels of poetic diction are not sufficiently in the pictures without them, the photographer is in a lous state, and it will take more than a title book to help him.

of the specimens are far-fetched enough. What

"Titles for Photographs." London: Office of "Focus," 6d.

business has this under "Architecture": "In gloomy cells and shades profound, the monk abjured a world he ne'er could view." The precise compliment implied in the following is a little elusive: "No spring, no summer's beauty hath such grace as I have seen in one autumnal face." And this is not much better: "Her hair is like the summer tresses of the trees," which seems to us to say little for either the hair or the trees. "A man he seems of cheerful yesterdays" might apply to one at present down on his luck. "The fresh spring's gaudy hue" may probably be useful when colour work has become more general, but what could be distinctly identified pictorially by "The gentle air of spring"? If anything could be made of it, we should suggest the title "There's air!" as even more free from ambiguity. A similarly elusive effect to photograph would be that which would picture "May glides onward into June," and he would be a close observer of Nature who could focus on the business as it progressed.

Many of these titles torn from their context convey only flippant ideas, which is a gross unfairness to the poet. "The daisies kiss our feet" induces the question, Whose feet? and our answering imagination includes those of tramps and gypsies, or of heavily shod cow-shed boys, and we do not envy the daisies. In the same way, "Up the sunny banks The trees retire in scattered ranks" makes us think of the advent of the camera fiend and its effect upon horror-stricken nature. "Yon cottage seems a bower of bliss" should surely have been classified amongst figure subjects, and so might "Dusky-sandalled Eve," whilst "The swell of summer's ocean" might fit a portrait of our friend Mr. Mortimer. The following, if shorn of its first two words, would also come in for figure work: "Autumn, like a faint old man, sits down."

We might go on for pages, pointing out the absurdities of lines wrenched from their context, of misquotation and mauled quotation, the latter quite painful in some cases. But we hope we have shown enough of the kind of thing by our few examples. At the end there are a quantity of real brand-new phrases never seen upon a picture yet, such as "Homeward bound," "Maiden meditation," "Toilers of the sea," "The bookworm," and many other "new and favourites." The best thing in the whole book is a list of synonyms, which appears to be well done, and is likely to be useful.

## SCREEN-PLATE PHOTOGRAPHY BY THE WARNER-POWRIE PROCESS.

last week the account of the Warner-Powrie screen-plate process, there were several matters which we were compelled to mention briefly as possible in order to avoid over-burdening the reader with technical details. The interest, however, in the process is sufficient inducement to add certain other matters to those already given. As regards the results, our readers are afraid, must possess their souls in patience until the opening of the Exhibition of the Society of Colour Photographers on September 30. The collection of examples of colour processes to be there brought together is likely to be of sufficient interest alone, yet the great and unique permitted by the Warner-Powrie process give good results, or supposing that the show will be visited by many people, this account.

### Process of Manufacture of Warner-Powrie Screen-Plates.

of general interest to give a more detailed description of the way in which the screen-plates are produced in the Warner-Powrie process. The surface of a plate of ordinary glass

is thoroughly cleaned and coated with a weak solution of gelatine, albumen, a mixture of the two, or of any suitable colloid body containing a proportion of alkaline bichromate. The mixture is very similar to the bichromatised fish-glue employed by photo-engravers. This coating having dried, the plate is exposed under a screen ruled with opaque lines which are double the width of the transparent spaces between them. The spaces correspond, as we shall see, to the exact width of the green and red bands in the manufactured screen. Those portions of the sensitised coating which are protected by the lines of the screen are not affected by the exposure to light, but the portions underneath the spaces in the screen are rendered insoluble on exposure. "Development" takes place in warm water, the mixture of glue and albumen dissolves in the unaffected parts, and there remains on the plate an enormous number of transparent lines in relief separated by depressions which are bare glass. The plates are then immersed in a solution of a green dye which penetrates the colloid bands, and forms a screen of microscopic green lines. The plate is then placed in a bath of alum or tannic acid,

which fixes the colour and enables the bands to attain sufficient intensity. Emerging from this bath, the plate is washed and recoated with a sensitive mixture and again exposed under the same screen, but with an adjustment of the carrier in which it rests to such an extent that the green lines just produced are protected by the double width lines of the negative. Between the portion of each band left uncovered and those stained green there is thus formed a narrow region which is equally protected by the opaque bands of the negative. On exposure being completed the plate is passed as before into warm water to develop the image, and it is then seen that a screen has been formed with a series of green lines and of transparent lines in relief separated by intervals narrower than the lines in relief. The plate is then plunged into a red dye bath and fixed and mordanted as before. Examined by transmitted light, the screen then presents a yellow colour, due to the mixture of the red and green rays of the two lines which are printed at this stage. It has now to receive a third impression of bichromated mixture, and is then exposed through the back without the interposition of any negative. The light thus reaches the sensitive film through all portions of the screen not occupied by green and red lines. As soon as exposure is completed it is again developed in warm water and transferred to a blue dye bath, which stains only those portions other than the red and green, and forms with them a continuous series of colours over the whole of the screen. As a result, the screen examined under a microscope shows a series of fine red and green lines separated by narrower blue lines, and to the naked eye examining it by transmitted light appears grey, due to the mixture of red, green, and blue.

From a practical point of view, this method, which consists essentially in leaving between the red and green lines a space which can be filled up with the blue, offers several advantages:—

1. It removes the difficulty of registration after the exposure of the screen.
2. It avoids all possibility of white interspaces and of overlapping of two bands of different colours; and
3. As blue is the colour which appears most intense in the screen, it is an advantage that the blue lines should be slightly narrower, and thus less visible.

The screen is coated with a suitable varnish, and is then ready to receive the panchromatic emulsion.

All the operations are conducted by a machine which brings the sensitive plate in contact with the screen-negative, and automatically adjusts exposure to variations in the temperature

and humidity of the air. Although the method is used by originators of the Warner-Powrie process for securing plates in lines, yet it is equally applicable to the making of screen-plate of any form whatever, and whether of regular metrical pattern or of irregular grain. The advantages, however, which are possessed only by a plate of linear ruling, already been pointed out in the previous article on the subject, yet as it is conceivable that for certain purposes of the process worker a screen of other pattern might be a desideratum, it is therefore of importance to recognise that the method of producing the screen-plates allows of any such variation being made.

### The Simplicity of Printing Warner-Powrie Colour Transparencies.

The danger of writing of the Warner-Powrie process in any description makes it appear complicated. Although the actual manipulations are necessary for the printing of a colour transparency, the actual manipulation is precisely the same as the making of a lantern-slide with the exposure broken up into three regions. There is no register needed between the screen-plate negative and the sensitive positive-plate, save that one set of lines be at right angles to that of the other, and printing is done by ordinary artificial light. Such, indeed, is the simplicity of the process that when the directions for the use of the colour plates come to be written they will read something like this:

"Lay the colour-negative film upwards in the printing-frame and lay upon it a piece of thin glass. Lay the positive-plate film down and expose with the printing-frame square to the light. At the end of ten or fifteen seconds, and without covering the printing-frame, shift the frame to a small distance to the rays of light, and continue exposure for a further time. At the expiration of this time again shift to another angle—the opposite direction—and again expose for the same time. The plate is then removed and developed in the developer at a fixed time."

Some other aspects of the Warner-Powrie process must be mentioned for future issues, but in the meantime we must ask for careful reading of the following articles by Dr. C. E. K. Mees and Mr. E. J. Wall. Dr. Mees, it will be seen, shows that the Warner-Powrie method is free from the disabilities of irreproductiveness which characterise an irregular grain process. The diagrams and text explaining the difference between the two require a close study in order that this new and very important side of screen-plate colour processes may be understood.

## PREPARING COLOUR-DUPPLICATES BY THE WARNER-POWRIE PROCESS.

In the history of all technical processes there are two distinct stages—the first, the period during which ideas occur to inventors, and patents are taken out. In every process these ideas and patents follow one another in rapid succession from many different sources. There follows a period of experiment and research on the part of the inventors which frequently eliminates a large number of the more impracticable of the processes. And then comes the second period, when the fittest, which have survived, become workable and practicable, and eventually make their way on to the market. It is this second stage which appears to be now commencing in the history of screen-plate colour photography, and it is because screen-plate colour photography has at last developed from the experimental stage into the region of practical manipulation that it has aroused so much interest and thought.

At first sight the advantages offered by a process in which only one plate was used, in which an ordinary camera was used, and in which only one exposure was required, appeared overwhelming, but it is clear that these advantages will be to some extent counterbalanced by corresponding disadvantages. In the case of mosaic plates the most serious disadvantage lies in the impossibility of reducing those plates; and one can make one,

and only one, positive; and second positives, and more especially prints on paper, are out of the question.

### Wanted, Prints on Paper.

It is generally felt that in any process of colour photography which is to be really successful it is necessary that prints on paper should be obtained, and those who have watched the development of colour photography will probably agree with me when I suggest that the great increase of interest in the subject during the last few years has been due not so much to improvements in methods of negative making as to the development of processes which render the production of prints on paper, if not at least practicable, so that the impossibility of printing of prints on plates is an exceedingly serious handicap.

### The Drawback of Reversal Processes

Another great difficulty of the process is the reversal which is necessary to transform the negative into the positive. This does not merely introduce a number of complicated chemical actions, but has a far more serious corollary. In order to obtain a satisfactory reversal by means of solution of the silver by an agent, such as persulphate of permanganate, it is essential that the plates should be thinly coated. If a thickly coated

containing a good deal of silver be taken, it is not possible to develop that silver through to the back in the highest exposures, and any undeveloped silver bromide left in the high-lights causes in the secondary development a veil of fog to spread over the entire plate, which degrades all the colours, even if it be very slight indeed. Consequently, it is necessary that the emulsion used for a plate intended for reversal shall be thinly coated, and shall contain very little silver. This produces at once the unfortunate result that such an emulsion can have but little latitude, and for this reason the range of contrast which a mosaic plate intended for reversal can render is very small indeed, it being, for instance, almost impossible to render the colour of a heavy foreground and also a blue sky above; and, moreover, it is necessary that exposures should be judged with considerable accuracy.

**The Warner-Powrie Screen-Plate Process.**

The new method of printing discovered by Mr. Powrie, and described in last week's BRITISH JOURNAL OF PHOTOGRAPHY, constitutes a step of the greatest importance in the production of four photographs. It enables us to make, not a positive but complementary negative, in which not only is black rendered as clear glass, and white as a dense deposit, but greens are represented as magenta-reds, blues as yellows, scarlets as blue-greens, and so on; and from this complementary negative we prepare any number of positives giving the correct colour rendering. It gives us, moreover, two separate and distinct methods of printing on paper.

Either we can prepare from the negative a set of non-linear transparencies which can then be printed by any method, such, for instance, as the convenient pinatype process, or it enables us from the colour positive to print on "Uto" paper, a process which, with the improvements which are sure to come in bleaching paper, will probably be of the greatest importance. It may be of interest first to consider the effect of the printing the positives from the negatives in the Warner-Powrie method with the aid of diagrams, which were originally published in the BRITISH JOURNAL OF PHOTOGRAPHY of July 5:—

Consider a colour negative having lines (horizontal in the original) of red, green, and blue, and imagine this to have been exposed to green light and developed so that the green stripe is black, the clear red and blue lines giving the plate a bright magenta colour. Now superpose this on a second line-screen placed at right angles over it.

Then Fig. 1 shows the appearance of the two plates, the squares which are crossed out being black and the clear squares (1 and 9) transparent and coloured. Squares 2, 3, 7, and 8 are black (or very dark), because two different lines are overlapping, while squares 4, 5, and 6 are black because of the deposit on the

	Red	Green	Blue
Red	1	2	3
Green	4	5	6
Blue	7	8	9

Fig. 1.

	Red	Green	Blue
Red	1	2	3
Green	4	5	6
Blue	7	8	9

Fig. 2.

green stripe. If a positive plate be exposed behind this we shall see the appearance shown in Fig. 2, where squares 1 and 9 are black and the other seven squares clear. Now let us consider the effect of printing these two plates in the method shown on page 689 of the "B.J." for September 13. Fig. 3 shows the appearance of the negative and positive plates superposed, giving

one line above and below the nine squares which we are considering.

If, then, we print as is shown in Fig. 1 of page 689, we shall get the positive shown in Fig. 2.

Now, if we print as shown in Fig. 2 of page 689, we shall superpose line 1 of the negative where 2 was, line 2 where 3 was, and so on. This will give us the positive shown in Fig. 4,

	Red	Green	Blue
Blue			
Red			
Green			
Blue			
Red			

Fig. 3.

which, superposed on the previous exposure shown in Fig. 2, will give Fig. 5 as the positive,

	Red	Green	Blue
Blue	1	2	3
Red	4	5	6
Green	7	8	9

Fig. 4.

	Red	Green	Blue
Blue	1	2	3
Red	4	5	6
Green	7	8	9

Fig. 5.

squares 1 and 9 being black from the first exposure, and 3 and 4 from the second.

Tilting the other way, as shown in Fig. 3 of page 689, we shall get Fig. 6 as the positive:—

	Red	Green	Blue
Green	1	2	3
Blue	4	5	6
Red	7	8	9

Fig. 6.

	Red	Green	Blue
Green	1	2	3
Blue	4	5	6
Red	7	8	9

Fig. 7.

which, superposed on the other two exposures shown in Fig. 5, will give Fig. 7 as the final positive.

In this way we have transformed the original negative in which the green line 4, 5, 6, was black, into a positive in which the only green line 2, 5, 8, is clear.

With the aid of Mr. J. H. Pledge I hope in a future article to confirm these figures with actual photomicrographs of the crossing line-screens.

It will be seen from this theoretical proof that the claim of Mr. Powrie that he has discovered a practical method of printing screen-negatives can be justified by the application of the same reasoning as was originally employed to show that mosaic

screens were not printable by direct superposition. A disadvantage which attaches to the method is that a point image is represented in the positive by three points, one from each exposure—that is, that an image which is the width of one line will be blurred to the width of three lines. Fortunately, owing to the great fineness of the lines, which are about 630 to the inch, this represents a point as an oval of only 1-200th of an inch in its greatest length, a blurring which for practical purposes may be considered as negligible.

#### Emulsion Grain and Screen-Plates.

The method employed by Mr. Powrie for preparing the screen-plates enables lines to be made of almost any fineness whatever. It may be taken that the Lumière autochrome plates are equivalent to a line positive where the lines are about 2,000 to the inch, but owing to the advantage which even distribution of lines gives in avoidance of juxtaposition of identical colours it is possible to use coarser line-screens than could be used in the case of irregularly distributed mosaics without a greater reduction being caused by the screen elements. It is sometimes forgotten that there is a distinct limit to the fineness of a line or mosaic filter, a limit imposed by the diameter of the granular agglomerates of the plate. For the purposes of development, the unit of a plate is the particle, a thing of considerably greater size than the plate grain, and consisting of an agglomeration of grains. If any portion of a particle be exposed, the whole particle becomes developable, and if the screen elements are of the same order and magnitude as the particles, it may happen that a particle is partly under a green element and partly under a red element. If green light be falling on that portion of the plate it will pass through the green element and affect the particle, but the whole particle will develop, and will obstruct not only the green element but also the red element, giving that particular green ray the effect of a yellow ray.

It may consequently be taken that the limit of convenient diminution of the screen elements has been reached whenever the lines are so fine that they are invisible under ordinary examination. From this point of view the Warner-Powrie screens leave little to be desired. With regard to colour-rendering, there are two decisive elements which will settle this. The first is the colour of the screens—that is, their absorption cuts—and the second is the sensitising of the plates. Complicating the question of colour-rendering must necessarily affect the question of the sensitiveness of the plate, which, owing to the fact that in any case the exposures must be considerable, should be enhanced as much as possible.

With regard first to the colour of the screens, there are two conditions here which must be fulfilled. The colour of the plate, when viewed as a whole, must be approximately neutral—that is to say, the plate must appear grey, as otherwise no pure whites

or greys can be obtained. In the case of the Warner-Powrie screens the plate is scarcely a neutral grey, being slightly violet in shade; this is a difficulty which improved screen dyes will doubtless remedy.

A second condition is that if bright colours are to be obtained the spectrum cuts of the filters must be abrupt, and have a little overlap. In the case of the autochrome plates this condition has been realised with great success by Messrs. Lumière the filters giving practically no overlap whatever. The Warner-Powrie plates, as at present made, give somewhat great overlap with scarcely sufficiently abrupt absorptions. It must be remembered that if narrow-banded filters are used speed will be sacrificed, as naturally narrow-banded filters pass less light than wide-banded.

In order to obtain correct rendering, the sensitising of the emulsion must be adapted to the filters. It is necessary that with the compensating filter used, equal density should be obtained beneath the red, green, and blue filters upon exposure to white light. In actual practice it is not convenient to make a compensating filter which affects the relative intensity under the green and red filters, and consequently in the sensitising of the plates the aim of the maker should be to equalise exposure under the red and green filters for the light which is to be used in the case of the negative plate daylight, and in the case of the positive plate any convenient artificial source, and then, if necessary, cut down the blue with a yellow filter of the required depth.

In the case of several commercial filters I have found practicable to obtain equality to daylight by the use of a yellow filter, which only increased the exposure from one and a half to two times, the red and green being already adjusted to equality. If the plates be coated with a gelatino-bromide emulsion as bathed it should be possible to make the plate apart from screen of a speed of about 250 Watkins. The mosaic screen will about a x20 screen, and with the compensator, say, at x40, giving a working speed of about 6 Watkins, a speed sufficient to make instantaneous exposures in bright sunlight and with a wide aperture lens practicable.

Should the manufacturing details be successfully solved the Warner-Powrie plates would seem likely to form an extremely simple method of colour photography; the exposures would have as great a latitude as is obtained with any plate at present and the scale of gradation would be as good. The exposure would not be unduly prolonged, and the manipulation would be as simple as the handling of an ordinary panchromatic plate, while the tilting necessary for the preparation of the positive could be made automatic by the introduction of a simple printing board fitted with the necessary stops to give the correct angle.

C. E. KENNETH MEES.

#### SOME NOTABLE FEATURES OF THE WARNER-POWRIE PROCESS.

THE article in last week's issue of the "B.J." will, I think, be marked out as the first announcement of a really practical process of colour photography, applicable to all subjects by the man in the street, the hand-camera worker, and the professional photographer. It is as great an advance on the starch-grain or other irregular grain process as these were over the ordinary three-negative processes, because one can obviously print on any surface. It promises one practically a matrix from which reproductions can be made, and, if the plates are but put on the market at anything like a reasonable price, it is the process of the future.

The points which particularly strike me are, first, the extremely ingenious method of making the filter-plate. Why some one should never have hit on the idea of using a ruled grating for the matrix and staining its image seems now incomprehensible. Both Professor R. W. Wood and Mr. Thorp had utilised diffraction gratings with different spacings for obtain-

ing colour photographs, and yet neither had thought of staining up the impressed image of the grating, relying solely upon diffraction for the results. It is obvious that, given a method of registering the lines, there is theoretically no limit to the fineness of the manufactured linear screen-plate. Practically, of course, there must be a limit.

The second and the most important point about this new process is the extremely ingenious idea of printing. Again, it is so perfectly obvious. The principle involved has been recognised unconsciously for years in connection with the Joly and McDonough results, and, curiously enough, has always been looked upon as an actual defect of the process. One has only to turn back to the photographic journals of 1900 to find that at the R.P.S. Exhibition some results were then shown and comments made upon the change of colour by direct or oblique examination. It is also a lecture experiment, which I have shown repeatedly, and I have yet a special slide with micrometer screw

shift the lines of the screen and cause a change of colour. was so obvious that by altering the direction of view or of light, one saw the correct colour exactly underlying its position, or one saw through the colour-screen element lying the right or left, yet no one had thought of utilising this for printing.

A careful search through most colour literature and the patents relating to colour photography shows that in the Brasseur-Sampolo patent, No. 8,390, 1896, the idea of using linear plates for printing is utilised, and may be briefly summarised as follows:—A linear-taking screen is used for making the matrix negative exactly as in the Joly and McDonough processes. To obtain each separate colour record from this matrix negative a black and white ruled screen, with the opaque lines the width of the transparent, is placed in contact with the near negative, and an exposure on a plate made. The black and white screen is then shifted so as to cover the portion of the linear negative already recorded in the second plate or transparency, and so as to uncover a new line. Again an exposure is made, and the process repeated for the third colour. In the same patent one finds the idea of using what one may call monochromatic filter with the complete colour record, which filter shall stop out two of the colours and only allow the third to act, and in this way three separate colour-sensation records may be obtained. This could obviously be used for obtaining three negatives from an "autochrome," for one has merely to use a deep-red filter that will completely stop out the green and violet to obtain a negative of only the red starch-

grain image, and the same applies with a green and violet monochromatic filter.

McDonough, in his patent No. 12,645, 1896, claims the method of a registering printing frame with micrometer screws for obtaining exact superposition of the linear negative with a paper or transparency plate also bearing the screen elements, and provided with particular figures, such as diamonds, half circles, or white lines for the purpose of registration.

The only other patent which at all bears on the subject is one by Brasseur, 28,798, 1903, but this applies solely to stereo work, the idea being to break up the stringy appearance by using one positive with the lines vertical and the other with the lines horizontal, but this obviously has but little to do with the duplication of results.

The fact that the Warner-Powrie process will enable us to utilise the bleach-out printing process will possibly give a fillip to the production of this paper in improved form—and there is room for improvement.

The one point on which at present we have no information is the emulsion, for upon this and the correct adjustment of the filters depends the faithfulness of the colour-rendering. This is an important matter if this or any other process is to be used for scientific work. As long as one confines one's attention to picture-making want of red sensitiveness or minima in the sensitiveness in any other region of the spectrum is not of much moment, but for the registration of pure colour it may be fatal.

E. J. WALL, F.R.P.S.

## THE FRILLING OF AUTOCHROME PLATES.

Many complaints have been made of the facility with which autochrome plates frill, so a remedy that is perfectly successful with itself may be of some service. It is not all original, as several of the details were suggested to me by others. I did not, however, find any of the suggestions to be effective alone, though a combination of them has proved serviceable.

Considering that alcohol is prejudicial to the plate, it seems rather curious that so much should be used in the first developer. Frilling nearly always seems to commence in this developer, and it occurs between the glass and the under-film, which strongly suggests a solvent action of the alcohol on the varnish at its under surface. I understand it is used in the lower film. Acting on this idea I reduced the quantity of alcohol in solution A from 100 cc. to 50 cc., and made up the difference with water. Then, again, it seemed evident that frilling should be less likely to occur in the first development if the plate was surrounded by a wide margin of unexposed emulsion upon which the developer would have no reducing action, therefore I used carriers with a wide white rebate. I took these precautions from the start, but they were not entirely successful. Frilling to a very small amount appeared in the rebates during the first development, and spread rapidly in the second development. It was checked slightly by strengthening the redeveloper, which is rather weak and slow in action. A double strength solution gives full density in less than two minutes, and so there is less time for the frilling to spread. The intensifier, however, settled matters by raising the film indiscriminately everywhere, so these precautions alone were unsuccessful. Finally, I have adopted the following complete method, and now do not get even a sign of frilling.

Solutions A and D are both modified, as described above, and the wide rebate is retained. When the plate is taken out

of the dark-slide a piece of softened red modelling wax is rubbed three or four times along each edge. This gives a slightly greasy coating, though no wax is deposited. The plate is then developed, washed, reversed, and washed again. After the second washing it is dried on a whirler, and is then bound all round with half-inch adhesive rubber surgical strapping. After this it is redeveloped and put through all the final processes.

The use of the tape was suggested by Mr. Sinclair, but it is a very troublesome matter to bind the undeveloped plate in the dark, though very easy to do it in daylight when the plate has been developed, reversed, and dried. The wide rebate, the reduced alcohol, and the wax perfectly protect the plate up to this stage. The wax might protect it longer, but it is safer to bind, as the next operation affects the extreme margins of the plate.

Mr. McIntosh, in his demonstration at the R.P.S., suggested the use of a whirler, and it has proved to be a most valuable accessory. My first plates were saved from complete ruin only by its use, for whirling is about the only thing that will stop frilling when it has once started.

The drying and binding of the plate adds only about five minutes to the time required for producing an autochrome, and it is better to spend it in these effectual precautions rather than in attempts to stop or remedy frilling that has already begun.

During my experiments I have noticed that solution C, the reversing solution, generally leaves a certain amount of scum on the film. This is removed by a piece of cotton wool while washing, as the water alone does not move it. This has nothing to do with frilling, but as I have seen no reference to it in previous articles it may be worth mentioning.

C. WELBORNE PIPER.

**AUTOCHROME PLATES.**—Messrs. Adams and Co. still have a good supply of these, together with screens, developer, etc., and are advancing prices on account of the difficulty in obtaining materials; the cost being for 9 cm. by 12 cm., 5s. a box of four,

and for 13 cm. by 18 cm., 10s. a box of four. Messrs. Adams also have ready a special "whirler" for use with the "Autochrome" plates, such a contrivance having proved necessary to prevent frilling, as mentioned in Mr. Piper's article in this issue.

## BRUSHES FOR THE OIL PROCESS AS WORKED BY M. PUYO.

IN response to our request for a reference to the precise description of brush used by him in the Rawlins oil process, M. Puyo has kindly furnished us with the following particulars and drawings, which are the only additional details necessary to supplement the very complete instructions for the oil process which, with M. Puyo's permission, appeared in our issue of August 30. M. Puyo writes:—"The brush, which I call 'pied de biche,' is so named from the hairs being those of

Fig. 1.

the 'putois' (polecat, or fitchet), and because the ends of the hairs form a surface inclined at an angle to the handle of the brush. Fitch hairs are, in my experience, much the best, as they are both supple and strong. The particular form ('pied de biche') of the brush, which has the hairs cut obliquely, is much more suitable for working on a surface inclined as in Fig. 2, for the reason that the hairs are then all perpendicular to the surface of the inked plate. The hand can then take up

Fig. 2.

a very natural position. Also, inking takes place more quickly owing to the position taken by the brush when pressure is applied to it, viz., a slight slipping movement towards the heel of the 'pied de biche.' M. Puyo buys his brushes from M. Bullier, 5, Rue Charlot, Paris, who manufactures twenty-four sizes of them, numbered 1 to 24, at prices from 80 centimes to 17 francs. The sizes which M. Puyo finds most useful are

No. 15, costing 5.80 francs, and No. 4, costing 1.20 franc. straight fitch brushes of the same maker are purchasable in fourteen sizes at prices from 75 centimes to 4.75 francs. The very small fitch brushes of the standing or straight pattern, mounted in a quill, are obtainable at prices which average from 50 centimes. They are very suitable for local working on the prints. As a guide to those of his colleagues of the P. Club who have taken up the oil process, M. Puyo has advised the following selection of brushes:—

	Fr.	C.
1 Fitch "pied de biche," oblique, No. 14, 15, or 16	5	
1 Fitch "pied de biche," oblique, No. 3, 4, or 5	1	
1 Fitch, straight, No. 7, 8, or 9	2	
1 Fitch, straight, No. 3, 4, or 5	1	
1 Fitch, in quill, No. 3	0	
1 Fitch, No. 7	0	

11

M. Puyo adds that the list of brushes issued by M. Bullier will be found to describe fully the varieties above referred to.

The pattern of the fitch brush cut obliquely, and described in our previous article by the literal translation of "hich foot," is indispensable, in M. Puyo's judgment, to the practice of the oil process. Without it M. Puyo would not think of attempting the process, but with it he regards himself as enabled to work more rapidly than is possible for any one armed only with straight brushes. The oblique brush, M. Puyo concludes, proves its merit when used by him in giving demonstrations of the oil process, since with it he can finish a 10 by 8 portrait in twenty minutes.

To this valuable addition to the notes which have already appeared, we would also supplement a word as to the "huilé minérale," used by M. Puyo in preparing an ink of softer consistency. We were in doubt as to its precise character, but are glad to learn from M. Puyo that our premise was correct. It is a light petroleum oil, as used for motor-cars. Petroleum ether, which is a slightly lighter spirit, may be used, but light petrol such as now obtainable in every town and in every village, may be taken as identical with M. Puyo's "essence minérale" and the "petroleum ether" occurring in our translation of August 30.

## THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

THE Exhibition of the Royal Photographic Society is at a glance pretty much like its forerunners. One looks around for new ideas and new sensations, and, in the pictorial section at any rate, one does not find them—no large romantic, German landscapes, for example, such as previous shows have displayed. But when the visitor looks attentively through the prints there is no denying that he finds evidences of cleverer, more observant, and more truly pictorial work than ever. For this reason the present exhibition will by no means rank as a dull affair. There may not perhaps be a very large proportion of oil prints, that latest development of the amateur; but there are a great variety of new ideas in the method of attack in pictorial photography. If this show could be compared side by side with one only two or three years ago the aspect would be striking. The fact is, that any grounds for the complaint of behindhandedness of the Royal Photographic Society are now entirely wanting. As

opposed to the Salon Exhibition, it is in reality much more "up to date," for the latter is but a throw-back to the days when the American had not yet arrived as a temporary backstop.

All who are interested in the question of colour photography will be able to make the acquaintance of the much-talked-of Lumière process in a darkened portion of the gallery, where the autochrome transparencies are on view. These, we think, will prove a great attraction to visitors in search of the wonderful. They will be dealt with fully in our next number, but in the meantime we may say that, as a promise of what is possible, nay, on the eve of accomplishment, colour photography, they are interesting and pleasing in the highest degree.

We should like to allude to a few of the leading prints in the pictorial, or "West," room. The president shows what, we think, will rank as one of his very finest productions,

ter Landscape." T. Steidel's "Marino," G. Bowley's "Spring Day"; "Sur la Porte" and "En Passant," by L. Bonne; "The Captain's Horse," by James Shaw; A. Elliott's "The Wilderness"; A. Gottheil's "Morgensonne"; J. Wynn's "Studying the Nude"; Dührkoop's "Portrait of an Lady"; "Beaching a Coble," by C. E. Wanless; "Kloster Chow," by Lette-Verein; "Nuit d'Été," by F. de Thierry; "Arienspiele," a splendid interior with figures, by O. Scharf; "Hüner-Hof," by Dr. Quedenfeldt; these make a list of

things which strike us in a first visit as being good and above the average. The Germanic element is strong in them, it will be seen, and we congratulate the Royal Photographic Society upon the co-operation of these talented Continental workers, to whom they have extended such wise and open hospitality.

The medals in the technical section are awarded to the Lumière Autochrome plate, irrespective of any particular result shown in connection with it, and to Professors Lowell and Lampland for photographs of Mars taken at the Lowell Observatory.

## THE PHOTOGRAPHIC SALON.

or three hours' study of the works at this exhibition confirms our opinion that it is a very good middling show—very good indeed. We do not wish our praise to be so faint as to be damnable, but no critic, we believe, will rate this year's play as a surpassingly fine one. The day is past, it seems, those one or two superlative pictures which put to shade the rest of an exhibition; photographers are levelling up so rapidly, the great ones are being very well imitated by the lesser, who then close, and occasionally those to whom we have looked for first-class things seem to fall off, as the phrase goes. Mr. Arbuthnot is one of these, and Mr. A. Marshall another, in this year's work. Of others, like Mr. Evans, and Mr. Craig Annan, whose reputations are well established, it would seem unreasonable to expect better and better things as the years go by, so that our work causes no surprise, because its high level of merit is expected of them. Such considerations lead one to admit that a good show may be also rather a dull one.

There is nothing in the way of a sensation it is the number of works—seventeen, in fact—accepted from Mr. Malcolm Arbuthnot. Certainly, most of these are to be warmly welcomed, and the exhibition, as a whole, is indebted to them for something of its attractiveness; but it does not appear why the whole seventeen have been hung in an exhibition of 183 pictures and sixty-seven senders. Half a dozen would have been more than twice the due average of Mr. Arbuthnot, and would have sufficiently furthered his reputation. We like his "Donkeyman" best of all for its action and the strength of the man's head. No other picture by the same hand has so fine a quality. "Shearing Sheep" is an unpleasant subject, and so is his "River," in which a great, dark, wormy-looking tree-trunk gnaws hard and ugly against a distance. In "Sheep and Adversaries," however, he has succeeded well in catching a sunny effect. "To Leeward" is a good example of a different class of subject, and shows the deck of a yacht heeling over, whilst the crew bestir themselves to the duties of their sport. Mr. Arbuthnot attempts all kinds of work, and with equal facility so far as "Decorative Study" is a view of water-fowl taken from a rather overhead point of view. It is neither very fine nor very good, unless its pronounced granulation place it in the last category. Photographers have a curious habit of submitting items as a view shorn of their setting and environment as specifically decorative pieces. Why this should be so we have never discovered, except when the results are applied as decoration to fire-places and such like, and then they are but banal echoes of a Japanese idea without a spark of anything really Japanese. "Evening Silhouette" is good in its design, which is made up of the figure of a man and the stern of a vessel over which he is stooping. Mr. Arbuthnot has repeated the idea in other works, and it is to be expected that he will continue to repeat it and have his due following of sycophantic repeaters also in future years. He himself seems to have borrowed not a little from Mr. Coburn in the matter. "A Vessel of the Olden Time" seems to want a touch of crispness somewhere. It is a very pleasing subject, well treated but for its monotonous

textures. The clock tower of "Westminster" is in ugly perspective, which causes it to topple over as by earthquake. In Mr. Arbuthnot's portraits we can make no preference. That which depicts Mr. Coburn with a most deplorably hopeless and lugubrious expression is more or less in the Coburn manner. How easily these manners and styles can be simulated!

Rudolf Dührkoop is represented by a dozen works. Many will prefer the fine and animated "Conversation" to all the rest. The sitters, if not actors, appear to be eminently fitted for a stage career. Their poses are clever, natural, and spontaneous, yet withal one feels that they are poses. It is in the lighting, the textures, the quality, and the rich, true tones that this work excels. "Portrait of a Lady" is a particularly strong study of a face full of character. A very different subject is afforded by "The Poetess," where the lineaments of Gabriele Reuter display a temperament highly sensitive and gentle. "Georgina" is a charming little plump-faced girl. More taking still, perhaps, is another of that motherhood series in which Herr Dührkoop excels. It is called "Mother and Child," and the action of the mother is quite delightful. The last work of this talented worker which we particularly admire is "Study of a Head," at once so delicate and strong in its admirable modelling.

Another prolific exhibitor is J. Craig Annan. He usually manages to achieve something smacking of novelty, and this year he shows a book-plate, too large by far except for use in portly folios; but it is to be presumed that he intends its reproductions to be much reduced. In a small version it would, we think, gain immensely. The design is that of a sort of Doctor of Laws—a lady, apparently. The face has a disingenuous expression, a little marring the general pleasantness of an undoubtedly clever photograph. Upon the lines of his highly successful "Stirling Castle," Mr. Craig Annan sends now "Stonyhurst College." The same crisp strength appears, with a mass of detail admirably broad in its management. But the sky is perhaps overdone. We admit that old copper engravings, of which this is so highly suggestive, were frequently topped by lowering clouds to support the depth of tone in the other parts; but we submit that a sky so strong in contrasts as this goes beyond the occasion. "A Botticelli," by Mr. Annan, does not represent "Sandro" himself, as the unrevised catalogue suggests, but a young lady whose face evidently bore for Mr. Craig Annan some resemblance to that of the type of Botticelli's Madonnas. He, therefore, has dressed her, posed her, and placed her in such a way before a print of one of the well-known votive pieces that her head comes before, and all but obliterates, the original Madonna, and she therefore appears surrounded by ministering angels in the approved fashion. Was the trick worth while? Does it not smack of a boy's prank, or, at least, of levity? And does this mixing up of real and ideal, of flat and round, of the pictured and the corporeal, add anything to our joy in either the altar-piece or the lady who stands in the way of it? Mr. Craig Annan's portraits, as we have already suggested, are no better and no less good than he has shown us before, and they

therefore do not call for any special remark in a short and selective review.

A. Horsley Hinton sends some extremely nice subjects, which are in some cases a little hurt by his evident over-anxiety to improve them. In the case of "The Creek," a sky of powerful contrasts robs a pleasing picture of verisimilitude with Nature—a pitfall which Mr. Horsley Hinton, as a leader of men, should have kept clear of. He has done so in "The Crag," which consequently is a better picture, though in other respects no better than the first. We are disposed to think "The Steam Saw" one of the best things he has ever done. It is modern in spirit, and therefore in accordance with the spirit of photographic work. It is truthful in its message, and although full of bustle and turmoil and commonplace material, does not lack poetry. Its chief merit is the feature made of the tones of smoke and steam respectively seen against the sky. Quite as true in effect is his "Windsor Castle," which gives convincingly the feeling of sunshine flooding across broad meadows. Sunshine, however, is quite absent from the "White Mill," a work of which the *modus operandi* has already received printed publicity. We confess to disappointment, and it is only fair to state that the author shares our feelings. The fact is that the over-accentuation of contrasted tones has "knocked the wind out of the sails" of the mill, which should have boasted of more sparkle, lit as it is, than the other parts could show.

F. J. Mortimer, of whom the world expects great things in the marine line, is represented by but one example, and that by no means as good as his past work. No one would presume to claim more observation of sea effects than Mr. Mortimer practises, but it is just a question whether he is not too ready to lose truth of effect in his enlargements. "A Gale in March" strikes us as flatter and more monotonous in effect than it has need of being, and it has a very strong family likeness to his other sea pieces by reason of the never-varying methods in enlarging that Mr. Mortimer employs. Its subject, and the forms of the waves, are as admirable and as fascinating as ever.

The work of Mr. Frederick H. Evans is likewise always the same in its methods, but as he does not enlarge, and thereby loses untold strength and charm for the sake of increased scale, we do not lament his constancy to a method that serves him well. "In the Courtyard, Pierrefonds," is a highly pictorial selection made in a building of great beauty, and teeming with romantic associations. It is, as a picture, a delightful bringing together of dark and light tones into a pleasing pattern. These tones never lose their character of richness and clearness, and though divided by positive edges, such as are inevitable in sunny stone-work, they are never hard. One can see from his work the processes of admiration and enthusiasm in Mr. Evans's mind as he views and selects his subject. This is the art with the capital A, and his perfect technique and execution—mechanics *in excelsis*—manifests every jot and tittle of it. At the foot of one of the outside staircases in the reconstructed mediæval castle, the *major opus* of Viollet le Duc, stands an equestrian statue of a warrior in armour. Can it be of the great Porthos himself? The placing of this statue and its perfect harmoniousness with the line of the architecture it adorns speak no less of the unerring taste of the photographer than of the genius of the architect. We must not dwell upon Mr. Evans's other works, "The Stairway, Palace of the Popes, Avignon," and "An Ancient Baptismal Font," except to say that the reliefs upon the latter are a study of great beauty in direct lighting, shadows, and reflected lights.

Charles Job is another worker who has done good service to the Salon in years past, and who now shows but one example, "On the Banks of the Arun." It represents sheep under trees upon a hillside, the sun flooding the valley beyond. In these pictures of sunshine it is not the mere forms of light and shade patches that make them lovely; it is something else, for which

a name is wanting. Feeling is a term that best expresses it, and this Mr. Job has secured, with the result that his pictures call up the precise sensations one feels in viewing a scene such as this, where the atmosphere is permeated with light as it flows through and beneath a canopy of trees. The composition is very happy.

F. H. Cliffe's two architectural works echo many qualities of Mr. Evans, of whom he would seem to be a disciple.

We feel that Mr. Benington is not going ahead so quickly as he might, for his record is not yet so long as to excuse a lack of further developments. "The House of Lords" is nice in its way, but we should have preferred it without the bridge which disports itself before Barry's masterpiece. Photographers are becoming obsessed by iron structures that are allowed to cut across the views which they obstruct and mar. The fashion will pass, we hope, as all fashions do. Mr. Benington, in his "Snowdon," has achieved a fine spaciousness of atmosphere without any unwelcome structure in the foreground, thus proving that such an adventitious aid is not needed to the effect. Two other landscapes by him are likewise good, but his work, as a whole, has not advanced.

Mr. Ward Muir takes the photographic long foreground and manages to produce a charming thing showing water lilies in plan, as it were, whilst the bank at the top of the picture gives some dark notes and objects "in elevation." He has other views of more traditional arrangement which should attract many admirers, though they call for no special remark.

Of the four works by Alexander Keighley "The Wood" pleases us best. It has a dignity and repose about it that makes an appeal; but, on the whole, we think that Mr. Keighley has not fulfilled his promise of other works. "The Melon Stall" is a little in the manner of Mr. Lewis, but it is too nebulous and wanting in strength of pictorial treatment to advance his reputation, or even to sustain it.

The father of modern oil-printing exhibits two examples of the process. They are both substantial evidences of the usefulness of this amenable method, and Mr. Rawlins has helped the movement by demonstrating that an oil print can take its place quietly among prints by other methods without advertising itself as anything out of the way or of unusual appearance. The snow piece entitled "And More to Come" displays no oily characteristics whatever. The surface and texture of the snow is extremely well given, and the dark sky of support is satisfactory but for a slight excess of granularity such as we have become inured to in "gum" prints. In any case we cannot quite see the logic of making a sky more granular than snow; but, apart from that, the little picture is full of charm. We prefer it to the more ambitious "Edinburgh," in which, as we like that.

"The Gondola Pool," by A. H. Blake, is a work of more freshness of idea in its selection. It shows a corner of Venice taken from a low point of view, such as one would have if seen from in a boat, and includes the landing-steps of a building in the middle distance, but not much above that level. Its gleam of sunlight gives it great pictorial value. "The Horse Guards" has also a deal of truth in its effect; but Mr. Blake's picture, "Cannon Street Station," is much less agreeable in its subject.

John H. Anderson likewise shows us a view of "The Horse Guards," not so taking as the other. We much prefer his "The Bridge," though we wish it were not so brown. It boasts a very pleasant effect. "Dordrecht" is similarly a most tasteful view.

If "Away to the West," by W. J. Clutterbuck, is an oil print, it is an example that should be studied by all tyros in the process, not for what to do so much as for what to avoid. He has shown the sun half-way below the horizon, but he se

to forget that the sky at such a time could not possibly graduate to an inky blackness at the south-west. He has also outlined the little black figure in the boat with a white line to represent an edge of sunshine upon it; but he has committed more than one solecism in performing this trick. It is all very well to get an effect, and one that is overdone is no doubt better than none at all, but it should not be attained at the cost of such glaringly obvious falsity to natural possibilities. We are glad to be able to turn to the same photographer's "In a Ligurian Valley," where the effect of sunlight behind figures is truthfully and beautifully rendered, to the great enhancement of the charms of a good picture.

A misty valley where evening shadows lurk is the subject of E. Ward-Thompson's excellent work, "Corrie na Creiche." We much admire the true relation and harmony of the sky and the vapour-veiled hills in this impressive work.

Two delicate and winsome studies of children, such as we have seen here from Mr. Will Cadby for years past, are infinitely to be preferred to his ridiculous "Snow Shadows," wherein the water-mark on the mount is more in evidence than anything else, save one small spot in this farce of a picture.

Though Mr. Mummery's "Farm Road" is a beautifully composed little evening piece, we think the more open and fuller "Fen Drove" his better work. It speaks so eloquently of the dull, drizzly weather that seems to belong by nature to the Fen country.

The clean-cut little gems of C. H. L. Emanuel are as exquisite as ever. It is difficult to make a choice between "The Sea Front" and "The Fishmonger's Shop."

(To be continued.)

## Exhibitions.

### KODAK REFLEX PHOTOGRAPHS.

As announced last week, there was opened on Thursday, the 12th inst., at the exhibition gallery of the Kodak Company, at 115, Oxford Street, W., a collection of enlargements from negatives made with the "Graflex" camera, an instrument which, as is well known, has attained very great vogue in the United States for all the purposes of Press photography, and the production of negatives of objects in the most rapid motion. The photographs to be seen at Oxford Street fully sustain this reputation of the "Graflex." A number of them were shown by the Kodak Co. at the recent exhibition of reflex cameras at "The British Journal of Photography," but one or two of especially interesting, not to say sensational, character are deserving of mention. One represents a horse turning a somersault in mid-air, which, while it is no doubt of special interest to horse trainers, is nevertheless a feat of instantaneous photography, and one for the obtaining of which a camera of the reflex type offers special facilities. Another example in which two horses in a steeplechase are seen surmounting the same hurdle simultaneously is remarkable for the positions of the animals' legs, and while such a coincidence can hardly be the result of the unusual skill in the use of a camera, yet the appropriate placing of this and the other subjects upon the plate exemplify the virtues of the "Graflex" camera as an instrument for practical work. The photographs should be seen by anyone interested in the serious production of photographs of sport.

There are also exhibited in the same gallery a number of articles of domestic utility with photographic enlargements. Often as such combination has been recommended to the amateur photographer we cannot recollect ever having seen a series of articles in which the idea has been so successfully carried out, but we must defer a notice of this departure on the part of the Kodak Company until we can suitably illustrate it.

At CAMBORNE last week an explosion of gas in a burnishing lamp used by Mr. J. Lukey, photographer, Trelowarren Street, caused a fire in his studio. Mr. Lukey had difficulty in reaching the door, and was rather severely burnt about the face and right hand. The stock of photographs, frames, curtains, scenery, etc., was damaged by fire and water.

### FORTHCOMING EXHIBITIONS.

- September 13 to October 26.—Photographic Salon. Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.
- September 19 to October 26.—Royal Photographic Society. Sec., J. McIntosh, New Gallery, 121, Regent Street, London, W.
- September 30 to October 25.—Society of Colour Photographers. Sec., Henry J. Comley, Surrey House, Stroud, Glos.
- October 5 to 12.—Bristol Photographic Club. Entries close September 23. Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.
- October 10 to 12.—Dumfries and Maxwelltown Photographic Association. Sec., T. Armstrong, 41, Moffat Road, Dumfries, N.B.
- October 16 to 19.—Rotherham Photographic Society. Entries close October 7. Sec., H. C. Hemingway, Tooker Road, Rotherham.
- October 17 to 26.—Edinburgh and Midlothian Industrial Exhibition (Photographic Section). Sec., A. T. Hutchinson, 15, Leith Street, Edinburgh.
- October 30 and 31.—Watford Camera Club. Sec., W. R. Gunton, 139, High Street, Watford, Herts.
- November 5 to 27.—West of England Industrial Exhibition (Photographic Section). Entries close October 5. Sec., A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.
- November 6 to 8.—Bedford Camera Club. Entries close October 31. Sec., P. C. Penny, 64, Harpur Street, Bedford.
- November 6 to 9.—Hackney Photographic Society. Sec., Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
- November 12 to 16.—Rugby Photographic Society. Entries close October 29. Sec., R. H. Myers, 13, Bridget Street, Rugby.
- November 19 to 23.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 25 to 28.—Lancaster Photographic Society. Entries close November 16. Sec., Walter Gunson, Manesty, Scotforth Road, Lancaster.
- Southsea Photographic Society. Sec., Gilbert Wood, 10, Pelham Road, Southsea.
- December 11 to 14.—Hove Camera Club. Sec., Stanley Read, 12, Old Steine, Brighton.
- November 28 to December 4.—Southsea Photographic Society. Sec., Gilbert Wood, 10, Pelham Road, Southsea.
- December 5 to 7.—St. George Co-operative Society Camera Club. Entries close November 25. Sec., George Anderson, 77, Braeside Street, Glasgow.
- December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

- February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between September 2 and 7:—

- CINEMATOGRAPHS.—No. 19,714. Checking apparatus for synchronously running cinematographs and talking machines. Jules Greenbaum, Thanet House, Temple Bar, London.
- DARK SLIDES.—No. 19,730. Improvements in dark slides for photographic purposes. William Watson, 803, Lea Bridge Road, Walthamstow.
- CINEMATOGRAPHS.—No. 19,758. Improvement in cinematograph films. Barrington Hooper, West View, Belvedere Road, Bexley Heath, Kent.
- CAMERA.—No. 19,779. Panoramic camera. William Arthur Case, 18, Southampton Buildings, London.
- CARRIER.—No. 19,853. Universal adjustment carrier for enlarging lanterns, for holding negatives, plates, films, and the like, for projection enlarging. Henry Ernest Bellamy, Stanley Mill, Factory Lane, Harpurhey, Manchester.
- FILMS.—No. 19,864. Improvements in packages for holding photographic films. Magnus Niell, 65, Chancery Lane, London.

CINEMATOGRAPHS.—No. 19,892. Improvements in and relating to cinematographs and like instruments. Reginald William James, 1, Queen Victoria Street, London.

PREVENTING DOUBLE EXPOSURES.—No. 19,902. Plate-saver and double exposure preventer. Samuel Lowe, 26, Market Square, Shirebrook, Derbyshire.

DEVELOPERS.—No. 20,050. Manufacture of new para-aminophenols especially suitable for use in photographic developers. August Zimmermann, 24, Southampton Buildings, London (for Chemische Fabrik auf Actien vorm. E. Schering, Germany).

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PREVENTING HALATION.—No. 28,376, 1906. The invention consists of an adhesive packing fabric of dark colour. The surface of a sheet of black waxed fabric is rendered adhesive by means of the application of a liquid capable of dissolving the wax, for example, French turpentine. The fabric is then put or pressed on the back of the plate to which it adheres, and is brought into optical contact with the same. The light impervious fabric prevents, when so affixed to the plate, any passage of light through the plate and consequently prevents refraction, so that not only is the halation avoided, but also a much sharper picture is obtained, as the light-rays, not being diverted, act on the sensitised coating of the plate with their full power. The fabric has the advantage that the plates are protected against breaking, and that the sensitized layer is more easily distinguishable when putting the plate in a dark slide. The fabric is removed before developing. Johann Hartelt, Grabschenerstrasse, 26, Breslau, Germany.

PRINTING FRAMES.—No. 19,943, 1906. The invention consists of a photographic printing frame having a sliding clamping strip, extending entirely across one end of printing frame, for the purpose of gripping a negative in an endwise manner, and at the same time

Fig. 1.

securing the sensitive paper between the edge of the negative and the clamping strip. To a rectangular rebated frame *a* is fitted a clamping strip *b* which is made to slide towards or from the negative *c* by means of a milled head screw *d*. Springs *e e* are sometimes fitted, as shown in fig. 1, to prevent looseness. The back *f* is held down by the bowed spring *g*, which engages under the staple *g¹* in the usual manner. In using the improved printing frame the back *f* is removed after turning off the spring *g*. The negative *c* is laid in the rebates of the frame, and the sensitive paper *h* is placed between the lower edge of the said negative and the clamping strip, as clearly shown in fig. 2. The clamping strip is now screwed up towards the negative, which is thus forced against the abutment *i*, and in doing so the paper as well as the negative is firmly held in the manner shown in

fig. 3. All that remains to be done is to turn the paper down on to the negative, replace the back, and proceed with the printing in the ordinary way. As will be seen, by reference to fig.

Fig. 2.

the entire subject is shown when the print is examined, and the paper hinging at *h¹* returns to perfect register. In printing from flexible films the negative *c* would be substituted by a plain glass plate, and the film as well as the sensitive paper

Fig. 3.

would be gripped at *h¹*. Thomas Richard Proctor, 13, Groombridge Road, South Hackney, London, and Houghtons, Ltd. 88 and 89, High Holborn, London, W.C.

ROLLER-BLIND SHUTTERS.—No. 6,785, 1907. The invention relates to certain improvements in the roller-blind shutter of Patent No. 20,800, 1905, and consists essentially in applying to the ratchet wheel or to the winding spindle a brake or friction device which will retard the recoil of the actuating spring when released. The shutter *A* is of the usual construction of the roller-blind type with a spring-actuated roller *B*, spring-actuated roller *C*, a winding spindle *D*, a ratchet wheel *d*, and a retaining pawl *E*. The retaining pawl *E* may be moved out of contact with ratchet wheel *d* to release the winding spindle *D* by the lever *A¹* as

Fig. 1.

Fig. 2.

scribed in the Specification of Patent No. 20,800 of 1905, or may be as more ordinarily constructed independent of such lever. To the ratchet wheel *d* we apply a brake *F* which is pressed against it to retard the recoil movement of the spring and winding spindle *D*. The brake *F* may be in the form of a spring affixed to the pawl *E*, which bears continuously upon the ratchet wheel *d*, and serves the double purpose of a spring to hold the pawl in contact with the wheel, and as a brake when the pawl is withdrawn as in Fig. 2. The spring brake acting thus is pressed more tightly against the ratchet wheel when the pawl is moved away from the wheel. The Thornton-Pickard Manufacturing Co., Ltd., of Altrincham, and George Arthur Pickard.

**MERCURY VAPOUR PRINTING APPARATUS.**—No. 8,075, 1907. The claim is for printing apparatus in which both the lamps and printing cylinder are stationary. The invention further relates to a suitable arrangement of the stretching-cloth or apron which holds the materials (tracing, sensitised paper, or the like) up against the fixed horizontally placed printing cylinder, as well as to an arrangement for protecting the printing material against the light while it is being placed in position, in such a manner that this work may be done conveniently without necessitating the lamps being extinguished meanwhile. Thomas Thomassen Gabroe, 12, Colbjørnsens Gate, Copenhagen.

**CYLINDER PRINTING APPARATUS.**—No. 8,817, 1907. An addition to Patent No. 16,390, 1906, in which a revolving glass roller 1 is mounted in suitable bearings in standards 3, a series of wooden or like rollers 7, 8, 9 with an apron or band 10 passing round same being also provided, such glass roller 1, and one or more of the wooden rollers 7, 8, 9, being geared together by toothed wheels 17 and 18 so that the surface of the former and the cloth

Fig. 1.

10 carried by the latter will (on the operation of the machine by hand or power) be caused to move at exactly the same surface speed.

The standards 3 carrying the glass roller 1 and the wooden rollers 7, 8, 9 are firmly secured to a base plate 4, which for the purpose hereinafter described is pivoted at 5 to the stand 6 on which the whole of the apparatus is supported.

In the interior of the glass roller 1 a suitable number of electric mercury vapour tubes 21 or high power electric vacuum lights

Fig. 2.

are mounted, and a reflector 40 is preferably arranged beneath such tubes to reflect back light that would otherwise be partly or completely lost.

Such mercury tubes or the like are supported in any suitable manner, and the electrical connections 22, 23 are preferably

arranged as shown when four of such tubes are employed, so that the two on each side are in series with each other, and each pair is governed by a switch 24 or the like, which switches may be coupled together by a rod 25 (see fig. 1).

When mercury tubes are employed it is necessary to cause the mercury to traverse such tubes from end to end, and for this purpose the entire apparatus is mounted on the transverse points 5 so that it can be tipped to bring either end of such tubes uppermost. It is also important that the mercury should be at the positive pole when the current is turned on, and to ensure this the automatic arrangement shown in fig. 2 is employed, consisting in a flexible connection between the lever of the switch and a fixed point of the stand 6, and which connection is of such length as to actuate such lever to switch off the current when one end of the apparatus is lowered, and switch it on when such end is raised.

If the tubes 21 become overheated their operation is interfered with, and a fan 27 adjacent to one end of the glass roller 1 is arranged, and driven by means of pulleys 28 and 29 and a belt 30 from the shaft of the roller 9, or in any other suitable manner, so as to create a current of air through roller 1, and thus keep the tubes 21 cool. James Warry Vickers, Finsbury Square Buildings, London, E.C.

### Cleaning Films off Old Negatives.

THERE is a right and a wrong way of doing this (says Mr. E. J. Wall in "The Photographic News.") The right way is to soak the films overnight, or longer, in a basin of fairly strong soda and water, and when ready, transfer them to very hot water. This will bring off the most obstinate films. They will be found to vary in their behaviour according to the brand of plate and the developer. Pyro seems to toughen the film more than hydroquinone and metol; anyhow, some films do not dissolve but peel off, and these are the easiest to deal with, and will often strip easily after the soaking in cold water solution without the hot water. I find that if a plate is seen to be fogged, or otherwise spoilt on development, and is put to dry without fixing, the film always peels off easily. Some films of softer gelatine do not peel off, but dissolve bodily when transferred to the hot water, and the glass only needs a rub with a piece of rag to clear it. The most difficult cases are those where the film is not soft enough to dissolve, but too tender to peel off; but if the bulk of the gelatine be scraped off with the edge of another plate, and the rest rubbed rather hard with the rag, these also can be got clean. The plates can be put into another bowl of cold water as they are cleaned, to wash off any soda or floating bits of gelatine before they are dried. A pile of negatives put to soak in a basin will be found to stick together like limpets as the gelatine gets wet, unless means are taken to prevent it. This is easily done by winding a length of string in and out of the plates, so that each is slightly separated from the next, and the end of the string also gives a useful handle by which the plates can be lifted one by one out of the hot water, which should be nearly boiling.

### Edging Autochrome Plates with Rubber.

We have found the following method satisfactory (says a writer in "The Amateur Photographer"). Mix the usual rubber solution, as sold for repairing cycle tyres, with twice its usual volume of benzole, and spread a patch of this to a depth of about one-sixteenth of an inch in the middle of a rather large glass plate. The plate bearing the rubber solution being taken into the dark-room, the edges of the Lumière autochrome plate are successively worked in the solution, the plate being held in a nearly vertical position. Each edge must be blotted on a sheet of blotting paper when the plate is removed from the patch of solution, and in turning the plate round to rubber the edges in succession, care must be taken to hold the plate by the edges, and not to touch face or back. All four edges having been rubbered the plate is leaned against the inside of a box that can be covered. In ten minutes or less the rubber solution will be dry.

## New Materials.

Fancy Border Positive Films. Made by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

A series of borders, reserved, almost severe, in their design, and therefore all the more suitable for the majority of occasions on which they should be used, has been placed on the market by Messrs. Marion for use with or without the "Gardiner's" vignetter, reviewed in these pages not long ago. The novelty of the introduction lies in the fact that the border is secured upon the negative in the first instance. A mask provided with the border films is fitted into the camera back so as to appear centrally upon the focussing screen, and the sitter being placed before a dark background is focussed with the mask in position. As a result, only this portion of the plate receives an impression, and on removing the dark slide from the camera the plate can be transferred in the dark room to a printing frame, and being exposed behind the border positive receives a negative impression of the design, which can be made bolder or fainter according to the discretion of the operator and the effect required. The negative is then developed, and any number of prints are then available without the labour incidental to double printing. The positive border films are supplied in half-plate and whole-plate sizes, the former at 12s. per set of four and the latter at 16s. The printing frame necessary for the latter part of the process is supplied at 2s. 6d. half-plate and 3s. 6d. whole-plate.

"Multisecto" Mounts. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

For use with the "Multisecto" repeating back, to which we were able to accord a favourable review some weeks ago, the firm of Fallowfield has now introduced a special line of cheap slip-in mounts for the suitable presentation of the "Multisecto" photographs. The ingenious way in which a number of as many of twelve different positions of a sitter may be obtained upon a quarter-plate must be known to those who have read our notice of the apparatus, but to others the circular issued by Messrs. Fallowfield may be recommended. Not only for such small sub-divisions as we hereby illustrate may the "Multisecto" be used, it equally provides for panel pictures on a quarter- or half-plate, or for other convenient divisions

A specimen of twelve positions obtained on a single quarter-plate with the "Multisecto" back.

of these two popular sizes. Under these circumstances it cannot be wondered that a series of mounts specially fitted for carrying the small photographs should be placed upon the market. In doing so Messrs. Fallowfield have wisely chosen a series of neutral tints of paper containing the minimum style of decoration for an effective mount. The tints are dark brown, dark green, slate grey, and

blue grey, many of which are supplied either with a stiff back, whilst all are obtainable with a thin gummed back, the print being simply laid in position over the cut-out aperture and fixed by moistening and pressing down the backing slip. The prices of the mounts run from 11s. per thousand (1s. 3d. per hundred) to 2s. per thousand, and sets of samples may be obtained for 6d. per set free by any photographer, or will be sent free to anyone at present using the "Multisecto" back. It may be of interest to state that a half-plate size of the "Multisecto" is in preparation for use with the popular 70s. sets.

### CATALOGUES AND TRADE NOTICES.

Mr. Andrew H. Baird, of 33-39, Lothian Street, and 2 Brighton Street, Edinburgh, sends us his latest price list of chemicals, minerals, and bacteriological stains. The contents are necessarily too numerous to mention here, but the list should certainly be in the hands of chemists and laboratory workers, and may be obtained on application to Mr. Baird as above. Particulars are also given of the "Junior" sets of apparatus for chemical experiments which are one of Mr. Baird's specialties, and are put up in two sizes, 10s. 6d. and 21s., the sets of chemicals for use with the same being 7s. 6d. and 18s. respectively.

THE "TIMES" ON COLOUR PROCESSES.—Passing from the pictorial section to the technical and scientific one encounters an abundance of results on the Lumière autochrome plates, and one may assume that these examples, about 100 in number, represent the process at its best. A walk round the gallery in which the examples are arranged brings us face to face with some of the best work by Mr. Comley, Mr. Klein, and Mr. Gill, all of whom employ the older three-plate method, and, after looking at these exhibits with their clean and unclouded brilliancy, the observer may well return to the autochrome department and ask himself whether the latest advance is an advance in reality or only an easy way of obtaining a second-rate or third-rate result. It may, of course, be urged that the three-plate heliochromes at the end of the gallery are all still-life subjects, whereas the Lumière exhibit includes landscapes and portraiture. Let us then descend to the court below and see what Mr. Sanger Shepherd has to show. Two as delightful studio portraits as one could wish may there be inspected; the flesh tints, which are the weak point of the Lumière pictures, are almost identical, one being taken with a total exposure of twenty-five seconds and the other with an exposure of fifteen seconds, these times include the time involved in shifting the camera back. Further, Messrs. Sanger Shepherd show brilliant lantern slides by the three-colour process, slides which only require an ordinary lantern and ordinary light.

CHARGE AGAINST A CANVASSING PHOTOGRAPHER.—At the Shrewsbury Police Court last week, George Boffin, Helsby, Cheshire, photographer, was charged with obtaining 2s. by false pretences from Sarah Ann Chetwood, Loppington. Prosecutor stated that prisoner came to her house shortly before February 8 last, and asked her if she would have the children photographed. Witness agreed, and prisoner took the photograph. On February 8 he called with one photograph and asked her if she wanted any more. She said she would have two more. Prisoner then said he must have the money for them then, or he could not possibly bring them. She paid him 2s. for them on his promising to send them to her by post on following Wednesday. Prisoner gave her a receipt which was undated and unsigned. She had never received the photographs. Bennett Mayo, travelling photographer, stated prisoner was in employment for about twelve months up to July this year. In February he was working for him on commission. His duty was to get orders and bring them in, and he would receive back photographs when done and deliver them. Cross-examined prisoner, witness admitted he could not say whether he had the money or not for the photograph produced. P. C. Fryer said he received the prisoner in custody from the Frodsham police. In regard to the warrant prisoner said he had paid the money to Mayo. Bench retired, and on returning the Chairman said they must satisfy the prisoner the benefit of the doubt, and he would be discharged.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

### SATURDAY, SEPTEMBER 21.

London Photographic Club. "Outing to Sea Mills and Coombe Dingle."  
London and District Photographic Society. "Outing to Wanstead Park."  
London Amateur Camera Club. "Outing to Rothessay."  
London Photographic Society. "Outing to Keston."  
London and District Photographic Society. "Outing to Wimbledon Common."  
London Suburban Photographic Society. "Outing to St. Paul's Cray."  
London Polytechnic Photographic Society. "Outing to Loughton."

### MONDAY, SEPTEMBER 23.

London Camera Club. "Pinatype Process of Colour Photography." Demonstrated. Fuers! Brothers.

### TUESDAY, SEPTEMBER 24.

London Photographic Society. "Outing to Wandover and the Chilterns."  
London Photographic Club. "Business Meeting."  
London Camera Club. "British Trees." J. A. Lash.

### WEDNESDAY, SEPTEMBER 25.

London Middlesex Photographic Society. "Retouching." G. F. Barwell.  
London Camera Club. "Lectures by Messrs. Crick, Spink and Wilkinson."  
London Camera Club. "Half-Day to Hoylake."  
London and District Photographic Society. "Home-Made Platinum Papers." Mr. Biss. Competition, August 24 Prints.

### THURSDAY, SEPTEMBER 26.

London Photographic Society. "The Carbon Process." Messrs. Conolly and Ashford.  
London and Provincial Photographic Association. "Open Night."  
London and District Photographic Society. "Making Toned Lantern Slides." E. G. Collins.

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, 13th inst. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, A. Mackie, Scamell, Lang Sims, H. C. Spink, C. H. Skilman, and R. Fellows. Mr. H. C. Spink, president, in the chair.

The names were read of new members who had joined the Association since the last committee meeting in June, numbering twenty.

The Hon. Secretary said that naturally he had had a good deal of correspondence with members in reference to the new Workmen's Compensation Act, and probably all the more far-seeing of their members had realised their responsibility and had provided to that effect by insuring through the Association or otherwise, but he was sure that many failed to recognise the position the Act created and had not protected themselves.

Mr. S. H. Fry pointed out that as poisoning by chemicals was included in the Act as the equivalent of accident, and as it was obvious that some individuals were particularly subject to it, it would be necessary, in filling in the proposal form for insurance, to specify any employee who had this predisposition, and, moreover, it would be necessary to state this fact in the references, and also to ask whether this predisposition existed in any form for reference.

The Hon. Secretary said he had been endeavouring to make arrangements with Mr. H. J. Comley to give them a talk on colour photography from the professional's point of view, illustrated by samples, etc., at one of their members' meetings, and the fixed had been made for the members' meeting on Jan 10 next.

The Hon. Secretary reported that two conferences had been held by representatives of the Artistic Copyright Society, but unfortunately so far they had not been able to find any solution of the "marking" difficulty satisfactory to both sides. The matter was under consideration.

A report was read from Mr. H. J. Comley, who had been authorised to take proceedings at the cost of the Association against a number of free portrait dodgers working in his neighbourhood. It was noted that the guarded manner of proceeding left no opening for a criminal prosecution, but certain cases were chosen, and, through a solicitor, summonses were issued in the County Court against the Fine Art Co., Manchester, through their local manager at Leeds, for the return of certain photographs obtained under conditions of misrepresentation. In a few days a representative of the company called upon the solicitor with the photographs and paid the cost of the summonses and nominal damages of 1s. in each case.

Mr. Ellis said those present would regret to learn that Mr. Martin Jaolette had undergone a somewhat severe operation, but happily he was on the way to recovery. It was unanimously decided to wish to Mr. Jaolette a speedy return to health.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting on the 12th, Mr. Herbert C. Rapson in the chair, Mr. W. T. Wilkinson spoke upon "Ortho Plates for Landscape Work." It had been stated, he said, that photographers were using the wrong end of the spectrum, utilising only the blue rays, and not the yellow and green, but ortho plates had altered this, and we were now enabled to use all the rays. A couple of prints of a football team in jerseys of yellow with gold stripes were here shown, one on an ordinary non-colour plate, and the other upon an ortho plate used without screen, the difference in the rendering of the jerseys being very marked. Red and yellow, said Mr. Wilkinson, could be fairly well rendered upon an ordinary plate, whilst if blue were present an ortho plate would have to be used to obtain anything near a correct rendering. Further, the light-filter, or screen, would have to be adjusted to the plate in use, some plates needing a far deeper screen than others to obtain a proper rendering. Results were shown upon plates with and without the filter. The lecturer generally used K1 and K2 screens of Wratten and Wainwright for his work, and found that these gave all that was required except for copying paintings, when the K3 screen was useful. Mr. Stretton asked if Mr. Wilkinson would use the same developer and method of development when using an ortho and non-ortho plate upon a given subject? Mr. Teape thought that the ordinary photographer did not study, and did not understand development to the extent he should, but took what the plate-maker gave him in the way of plates and screens, and was satisfied with the results. The exposure should be of such a nature as to leave a reserve power in his hands if needed.

## Commercial & Legal Intelligence.

A WEST-END BANKRUPTCY.—Statutory meetings of creditors and shareholders of the firm of Turler and Co., Ltd., photographic dealers and jewellers, of 4, Great Russell Street, W.C., were held at the offices of the Board of Trade, 33, Carey Street, W.C., on September 13. The creditors appointed Mr. E. H. Hawkins, accountant, of 3, Barbican, E.C., as liquidator, but the shareholders' meeting, in the absence of a quorum, was adjourned for a week.

A COPYRIGHT CASE.—In the Chancery Division of the High Court of Justice last week there was an application by Agnew and Sons to restrain Clarke and Davies from infringing the copyright of "Harmony," the well-known picture by Mr. Dicksee, R.A., which is in the Tate Gallery.

Mr. Craies, who appeared for the plaintiffs, stated that the defendants had photographed the picture with a view to making it the subject of a picture postcard.

Mr. Frank Dodd, on behalf of the defendants, said that he was instructed to submit to a perpetual injunction. He would also have to pay damages. He desired to add, however, in some mitigation of his clients' conduct in taking the photograph, that copyright pictures were usually marked with an asterisk in the Tate Gallery catalogue. There was no asterisk attached to "Harmony," and the authorities at the gallery had gone so far as to remove the glass from the picture in order that it might be photographed.

Mr. Justice Parker granted the injunction, and, the plaintiffs not agreeing to accept £5, ordered an inquiry as to damages. He also made an order for delivery up of photographs.

THE RETURN OF A PHOTOGRAPH.—A young woman asked Mr. Fordham at North London Police-court to assist her in getting back a photograph. She had given it to a photographer to copy. She had received the copy, but not the original, though the photographer kept promising.

Mr. Fordham: What value do you put upon the photograph?

The Applicant: Oh, I don't know. But I valued it very much.

Mr. Fordham: How much do you think it would realise in the open market? Probably not more than a penny. And all the order

I could make in such a case would be, "Return the photograph, or pay its value, one penny." You might go to the County-court; but I will see if I cannot get it back for you in another way. The inspector on duty will make inquiries, and, unless it is spoilt or lost, I dare say he will get it.

## News and Notes.

THE BRISTOL Photographic Club's Exhibition next month will be arranged and hung by Mr. Alvin Langdon Coburn. It will be remembered that Mr. Coburn hung the London Salon last year.

THE ANNUAL EXHIBITION of the St. George Co-operative Society Camera Club will take place on December 5, 6, and 7, the closing date for entries being November 25. Further particulars and entry forms may be obtained from the exhibition secretary, Mr. George Anderson, 77, Braeside Street, Glasgow.

MR. JOHN OWEN, a well-known photographer of Newtown, where he had carried on business since 1865, died on the 7th inst.

THE VICTOR SPECIALTIES, circle and oval trimmers and mount cutters, are in future obtainable from the Victor Co., 99, Highgate Road, London, N.W. Telephone, No. 941 North.

HERR PAUL HANNEKE.—In reference to our recent review of the volume of formulae, by Herr Paul Hanneke, we must correct the statement that Herr Hanneke is a member of the scientific staff of the Actien-Gesellschaft für Anilin-Fabrikation.

MESSRS. JOHN WRENCH AND SON announce that they will be pleased to send a copy of their new art catalogue of lanterns and accessories and cinematographs, gratis and post free, to any interested in optical matters. Application should be made to the above firm at 50, Gray's Inn Road, London, W.C.

A VERY enjoyable amalgamated outing of the Hove, Worthing, and Southsea Camera Clubs was carried out on Saturday last, 14th inst. Quint old Rosham having been selected, the three clubs met there. During the afternoon many exposures were made, the lighting over the creek being particularly fine. The ancient church also received its share of attention.

ON SATURDAY, 14th inst., Miss Isabel Traill Taylor, daughter of Mr. and Mrs. J. Hay Taylor, of Bleak House, Wightman Road, Hornsey, and granddaughter of the late Mr. J. Traill Taylor, was married to Mr. Edgar V. Reading, son of the late Mr. Edmund Binfield Reading, of Bournemouth, at St. Peter's Church, Hornsey. After the wedding about forty guests attended the reception at Bleak House. The honeymoon is being spent at Bournemouth.

"PICTORIAL GUIDE TO UPPER CLYDESDALE" is an interesting booklet, which, as its title indicates, is specially devoted to that portion of Scottish scenery found in the upper valleys of the Clyde, a district which, though one of the most beautiful in Scotland, was until quite recent years comparatively little known. To meet the requirements of present-day visitors, Mr. Norman Hunter, of The Studio, Port Glasgow, has published the above guide book, which gives a brief description of the most important places of interest in the neighbourhood, the literary part being written by Mr. George Haddow and the pictorial portion supplied by Mr. Hunter from photographs specially taken by him for the purpose. Both illustrations and letterpress are well printed on good paper, and we heartily congratulate Mr. Hunter on the excellent character of his work. The price of the book is 1s. 6d., and it may be obtained from Mr. Hunter at the above address.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—It is no easy matter to compile a syllabus which shall meet the tastes and approval of all members of a photographic society, but anyone must indeed be hard to please who is not satisfied with the fare provided for him by that most indefatigable of secretaries, Mr. Charles F. Inston, as indicated in the winter syllabus of the above association just to hand. Among the demonstrations we note the latest developments in ozobrome and oil printing, whilst the lantern lectures should prove of special interest to tourist photographers, as they deal with all kinds of scenery both at home and abroad. Provision has also been made for the requirements of those specialising in various branches of photography, such as natural history, portrai-

ture, etc., and the lecture entitled "The Wonders of Light," which the session will open on September 26, should draw a crowd of house. Photographers living in the vicinity of Liverpool who are not yet attached to any photographic society cannot do better than communicate with Mr. F. C. Inston, Percy Buildings, 9, Ebbw Street, with a view to throwing in their lot with the "Liverpool Amateurs."

MR. E. MERCK, of London and Darmstadt, sends us a copy of his annual report, which, though in no way connected with photography, but dealing with recent advancements in pharmaceutical chemistry and therapeutics, and intended only for chemists and the medical profession, is of value as illustrating the thoroughness with which everything connected with the house of Merck is carried out, a quality which naturally extends to the photographic chemicals manufactured by the same firm, well known to our readers.

R.P.S. LECTURES.—The following lectures will be delivered at the New Gallery:—Saturday, September 21, "Eight Hundred Miles up the Nile," by R. Falconer Jameson; Monday, September 24, "South Africa in 1906" (the views are illustrative of Cape Colony, Natal, Orange River Colony, The Transvaal, Basutoland, Native Gold and Diamond Mining, Travelling, Thunderstorms, School Agriculture, Ostrich Farming, Veldt, Forest and Mountain Scenery, etc.), by Harold A. Atkinson, M.A.; Thursday, September 27, "In the Land of the Vendetta," by Rev. T. T. Norgate, F.R.G.S.

CANVASSEER'S METHOD.—The "Yorkshire Post" publishes a further contribution to the letter which we reprinted last week describing the method of the so-called "free-portrait" canvassers. The writer says:—Some time ago a member of this "persuasive society" was successful in obtaining at my house two photographs under the promise of supplying "free of charge" an enlargement of each having conferred on me the honour of being the party selected from the neighbourhood in which I then resided to be presented with "free copies" of same, "just as an advertisement." On hearing of the matter, I refused to have anything to do with it, but the "genius" was so anxious that I should benefit by the offer that he deposited the enlargements inside the door and rode away on his bicycle. About a fortnight later I was the recipient of an invoice for one guinea, which they expected me to pay for the "free copies." I took no notice of this, with the result that they then commenced their "bullying tactics" by sending me a letter threatening legal proceedings. To this I replied, saying I was quite prepared to meet such proceedings, which would no doubt give the public an opportunity of reviewing their business principles. I hardly need say that their threats were not carried out. They incurred more than two years ago. Their "fine art specimens" were still in my curio chamber."

TO MEN OF RESOURCE.—The following extract from the "Globe" will show what is expected from the Press photographer in carrying out editorial commands for "red-hot news in photographs":—"A somewhat discreditable incident occurred during a wedding at St. Trinity Church, Sloane Street, last week. While the bride, Lady Edith King-Tenison, was being led to the altar, a photographer stealthily made his way to the pulpit steps. All eyes were upon the bridal procession, and the man with his camera succeeded in reaching his goal unobserved. The ceremony had scarcely begun when he ascended the steps, and in another minute had his knee in position on the altar ledge and focussed on the bridal group. The tell-tale click of the apparatus, however, attracted the attention of the verger to the intruder, and, hastening to the pulpit, the official ordered the man to retire. The movement of the verger diverted the attention of the congregation for the next few moments. Finally the intruder was ejected, but he had secured a picture of the wedding party at the moment that the marriage vows were being taken. It seems that the photographer had been refused by the vicar permission to take a photograph from the gallery. Then, instead of leaving the church as was believed, he mixed with the congregation, and gradually made his way to the pulpit."

SCHOOL OF PHOTO-ENGRAVING AND LITHOGRAPHY.—The forthcoming session of the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., opens on September 24, and the prospectus can now be obtained by interested students. The school, which is under the direction of Mr. A. Newton, is open only to those who are genuinely engaged in business.

ness in any branch of the photo-mechanical, photographic, designing, illustrative, lithographic, engraving, and printing crafts, no provision whatever being made for amateurs. Of the various classes held, some are concerned with the more artistic side of the work, others with the technical and scientific; there is, however, no real line of demarcation between the two, either in intention or practice, and the division is made solely for convenience of teaching.

The Art section of the School should be of especial service to those artists engaged upon work for reproduction, as students in these classes will have the privilege of having selected work reproduced, and every opportunity will be afforded them to obtain a knowledge of the various processes and their limitations. The practical instruction given is not intended to replace workshop training or merely to increase manipulative dexterity, but is preparatory or supplementary to it, and has also for its object the giving to those engaged in one particular department of a craft a knowledge of the principles of their own and allied branches which, in the ordinary course of trade, they may not obtain. The lecture courses are for the purpose of explaining more fully the scientific principles and technical details of the various processes than is convenient during the conduct of the practical classes. Attention is drawn to the courses of lectures on special subjects by various experts, especially those on "Optics as Applied to Photo-Engraving," "Duplicate Plate Making," "Papers for Printing," and "The Chemistry and Physics of Colloids," by Dr. S. E. Sheppard.

The School is well equipped with the necessary appliances for study and practical work. It contains a photographic studio with four cameras and powerful electric light installation of modern pattern, including a large electric searchlight, dark-rooms, sensitising room, glass cleaning and intensifying rooms, tri-colour dark rooms, extensive etching and printing rooms—complete with electric light and modern appliances—a machine room containing the latest power machinery for mounting, router, beveller, saw, etc., block proving room with electric motor driven platen machine, collotype preparation and printing rooms with two presses and necessary equipment, a photogravure room, a reading room, and museum of specimens and examples. There are also two large rooms for lithographic drawing and a press room, as well as separate studios for design, antique, and life and costume drawing. The School thus provides every advantage and facility for those who wish to improve a knowledge of their business and their dexterity as workmen. In deciding upon a course of study, it should be remembered by a learner that, while it is very important for him to have a good general knowledge of the different branches of his business, it is of still greater importance that he should be able in actual every-day work to do one thing really well rather than a number of things only fairly well, and, this being so, students are required to concentrate their energies as much as possible, and not to attempt too much.

The Council may award certificates to those students who have attended approved courses of study and comply with certain conditions.

The School session is divided into three terms, the first extending from September 24 to December 20; the second from January 6 to April 15; and the third from April 27 to June 27.

Both day and evening classes are provided at the Bolt Court School, in each case only to those who can prove to the satisfaction of the Principal that they are connected with the trade. Among the various courses of lecture demonstrations and practical workmanship instruction mention should be made of those in the making of line and continuous-tone negatives, in three-colour block making, in the various printing processes for half-tone and zinc work by the enamel and albumen processes. Various other special processes of half-tone production, such as fine etching, mounting, proofing, and engraving are also in the hands of special instructors. In the lithographic and collotype departments all stages of the work and its commercial applications are taught by those commercially engaged in it. Photogravure and mezzotint engraving also come within the curriculum of the Bolt Court School, the staff of which within the last few years have every reason to be satisfied upon the large accessions of students and the success which the latter have obtained on their emerging from the school into the commercial use of the instruction they have there received in the reproductive crafts.

WATFORD CAMERA CLUB.—The annual exhibition will be held on October 30 and 31. There will be eight open classes, including a champion class and one for novices—that is, those who have not previously obtained an award in any exhibition. Mr. A. Horsley Hinton will judge the exhibits, and silver and bronze medals, together with a silver plaque for award in the champion class, will be placed at his disposal. Entries close October 24, and entry forms and full prospectus will be ready about the middle of October, when they may be obtained from the Hon. Sec., Mr. W. R. Gunton, 139, High Street, Watford.

## Correspondence.

### PHOTO-MICROGRAPHS OF STARCH GRAINS IN THE LUMIERE "AUTOCHROME" PLATES

To the Editors.

Gentlemen,—With reference to the note by Mr. Martin Duncan in your issue of 6th inst., Colour Supplement, pp. 68—69, on the "Microscopic Appearance of the Lumière Autochrome Plate." It is stated in the last paragraph that when observing with crossed nicols the characteristic cross marking of starch grains was not found. I send herewith a copy of a recent photo-micrograph of a portion of an Autochrome plate X500, taken with crossed nicols, which I think

shows the "black crosses" very well. The photograph was obtained with a dry  $\frac{1}{8}$  and No. 1 e.p.: plate Wratten Panchromatic. The brightest grains in the photograph are the red ones. I may add that I have not failed to notice the black cross in any of the plates of various batches of Autochrome I have examined up to the present.—Yours faithfully,

J. H. PLEDGE, F.R.M.S.

Research Laboratory, Wratten and Wainwright, Ltd, Croydon.

### SKIN AFFECTION AND THE TONING BATH.

To the Editors.

Gentlemen,—In reply to "Oak Side," I may say that I am suffering in just the same way with my hands, and no amount of ointment, etc., seems to do them any good. I have now taken to using boric lint, which appears to be efficacious. The lint should be damped and then wrapped round the fingers, and covered with oil-skin to keep them wet.

Fresh lint should be used each night and morning, until the

fingers seem to be thoroughly well blistered and new skin grows, and then I believe it is advisable to use some emollient to strengthen the skin. It is a somewhat tedious cure, but it is the only one in my case which appears to do any good, and I hope it may be of some service to others suffering in the same way.—Yours faithfully,  
6, Ribblesdale Road, Hornsey, N. M. DARTON.

#### DEVELOPER SKIN AFFECTIONS.

To the Editors.

Gentlemen,—As there has been so much correspondence *re* amidol poisoning and operators' fingers, I beg to place my experiences before the readers of the JOURNAL. I have experienced great inconvenience in the past with cracked and burst fingers. This I have attributed to amidol, which I use daily. I am, however, convinced that the trouble is caused by hypo in conjunction with different town waters. In 1904-5 I was a martyr to a great extent, my fingers being like raw meat. I tried all sorts of remedies with very little relief. My business then took me away from Leicester, when in time the sores healed up. I have now returned to the old town, and the trouble has returned. The reason that I feel so convinced that hypo is the cause of the itching blisters and bursting of my fingers is that I have been most careful to use one hand only for developing and the other for fixing, with the above result that the hand used exclusively for the fixing bath is at times so raw that it is agony to work. I have failed to see how one can successfully turn a large batch of prints, say a gross at a time, without getting the fingers wet up to the second joint, as previously mentioned in the JOURNAL; it is only necessary to use the finger tips for the purpose, but how about the prints at the bottom of the dish? I find that to rub wool fat well into the skin helps a great deal to turn out the hypo, and then afterwards to wash the hands well in hot water and bathe with rectified spirit. This stops the itching, but makes the hands very painful for a few minutes. Hoping this will open further discussion from more able pens than mine, I am, Gentlemen, yours truly,  
P. H. ADAMS.

45, Meynell Road, Hummerstone Road, Leicester.

#### BLISTERS IN BROMIDES.

To the Editors.

Gentlemen,—Your article and notes on blistering remind me of the old albumen days, when blisters were at times troublesome. An invariable cure was, after the batch of prints were fixed, to allow the water to flow into the dish and gradually diffuse the hypo until it was replaced by water only, and then continue the washing. This treatment was suggested to practical workers because hypo, being always very cold when freshly mixed, it was noted that the sudden change to comparatively warmer tap water caused blisters when the prints were lifted from the hypo and suddenly plunged into a dish of water of another temperature and density.

I certainly think that differences in temperature and density will account for the trouble in bromide paper, and I would recommend that every reasonable precaution be taken in this respect so as to get as near as possible equable temperature in all solutions.

Some workers use an acid fixing-bath day after day without change. In this case it would at certain seasons or under certain conditions become warmer than the tap-water. This might cause blisters. Other workers mix their hypo just as required by "shoving" a handful of hypo into a dish and turning on the tap by rule of thumb.

The best plan is to mix up hypo in large quantities of saturated strength, so that it has time to adapt itself to the normal temperature. Then when it is diluted to proper fixing strength it will be of the same degree as the tap water. But whenever possible, adopt the diluting system mentioned above.—Yours faithfully,

R. E. W.

THE LETO OUTING.—The employees of the Leto Works, Edgware, held their first annual outing on Saturday, 14th inst. The staff and their friends met at the works at midday, and proceeded in brakes to Essendon, where a most enjoyable day was spent. The weather being favourable, the various races and other outdoor amusements were greatly appreciated, the day's programme proving a great success in every way.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

#### PHOTOGRAPHS REGISTERED:—

- J. Busby, 31A, Market Place, Preston, Lancashire. *Flashlight Photograph of Archbishop Bourne and Bishops at Catholic Truth Conference.*
- J. W. Tattersall, 64, Blackburn Road, Accrington. *Photograph of Alderman J. Kenyon.*
- D. Ryan, 1, Ardilaun Villas, Dollymount, Dublin. *Photograph of Decorations and Tomb Interior of Daniel O'Connell, Glasnevin Cemetery, Dublin.*
- W. R. N. Gard, 57, St. Kilda Road, West Ealing. *Photograph entitled, "A Bit for Dogie."*
- A. Russell, 6, Wilde Street, Liverpool. *Photograph entitled, "Bound for the Rio."*

R.P.S. STUDENTS' FELLOWSHIP.—In your issue of the "B.J." for March 22 of this year, I see in the "Answers to Correspondents" a paragraph headed, "Examination." In this paragraph you mention "Students' fellowship application arrangements of the R.P.S." Can you give me any further information of these arrangements, as, although I have mixed with members and fellows of the R.P.S., I have never heard mention of this before.—STUDENT.

They have been drawn up by the Royal Photographic Society, from whom a printed copy is, we believe, obtainable. We advise you to write the Secretary, 66, Russell Square, W.C.

ROLL FILMS.—I have lately bought a Kodak No. 2 Brownie. I developed two films, and found it was all right; but unfortunately I have spoilt three films this week. I cannot make out what is wrong. I think it must have gone wrong in the developing tank. After it had been in it twenty minutes I took it out, and found most of the film was dry. I enclose the incomplete film with this letter. Can you advise me in the matter?—F. KING.

We cannot from your information. You had better take it to the depot of the Kodak Co. nearest to you, viz., 115, Oxford Street, W., where your difficulty can be certainly explained.

POSTCARDS.—Could you tell me where I could buy postcards that have a slip in the corner that you can put the stamp photographs in? I saw some on sale, but do not know where to get them. I should be obliged if you could tell me.—J. W.

We have not seen them. Better write to Messrs. Fallowfield, 146, Charing Cross Road, W., or Messrs. Butcher, Camera House, St. Bride Street, E.C., both of whom make a special line of postage-stamp materials.

BITTEN.—As you have taken criminal proceedings against the man, and he was punished for the offence on which he was charged, we do not see what else you can do, particularly as you do not know where to find him. You might have charged him with embezzlement at the time you prosecuted him for the theft, had you chosen to do so.

JACKSON (Southsea).—If you are, as you say, an operator, you should be able to answer your six queries much better than we possibly can, as we have no idea of the capital you can command, the style of business you propose to start, the kind of work you are capable of producing, or your tact in business matters. You will be able to get, approximately, the population in different towns from the "A.B.C. Railway Guide." We can also refer you to the article on the purchase of a photographic business ("B.J.," May 24, 1907, p. 382), which deals with the general matter of your inquiries.

STUDIO QUERY.—I am thinking of building a studio on the roof of a back addition of the house, but I can only get a length of 15 ft. and a width of about 12 ft. Do you think this would

long enough for ordinary professional work? I may mention that by enlarging the opening to it from the room, I could have the camera in it, and in this way get a length of 10 ft. more. Do you think this worth while, as it would entail no extra expense? Your opinion will greatly oblige.—C. H. G. It would certainly well repay for the additional cost. With studio only 15 ft. long very short-focus lenses only could be used, and with them the perspective in the pictures is lent, and the pictures, as a rule, by no means satisfactory. So short a studio there is always a difficulty with groups of full-length figures; but with the additional length mentioned these difficulties will be avoided.

**HORSE AND TRAP.**—Will you please tell me if I am liable to have to pay a tax on a light trap I have? My business is largely in taking photographs away from home, sometimes long distances, and I find it necessary to have a horse and trap to carry the apparatus, often 15 by 12. The Income-tax people say I must pay duty upon it, as it is used for pleasure, which it is not, except that now and then I may take my daily for a drive on Sundays. The collector says I can avoid it like, but he does not think I shall do any good by so doing.

**BUSINESS.**—If the vehicle is used solely for business purposes it is exempt from duty, but if you use it also for pleasure, as you apparently are doing, you will have to pay the tax, we expect. You might appeal against it; it would do no harm, though we doubt if you will be successful.

**IMAGE.**—I enclose herewith prints from two negatives I recently took of the interior of a church. You will notice that each of them there is a faint image of a window. The negatives were taken the one immediately after the other, the camera not having been moved at all, and they are both alike. The curious part of the matter is that this window is quite the side, and cannot be seen on the focussing screen, as I have been with the camera again on purpose to see if it could, but I did not take another negative then, as the light is very bad. Have you ever seen such a thing before?—ANDRAY.

**YES.** We have seen several such samples. The ghostly image due to a minute hole in the camera, which has acted as a bell-hole camera with the prolonged exposure that the plate made. From the position of the secondary image, we surmise the hole is in the bellows. Take the camera, with the bellows fully extended, out in the sunlight, remove the focussing-screen, the lens, and examine the bellows from the inside, keeping the head covered with the focussing-cloth. By turning the camera about in the sunlight you will be able to see where the hole is. The remedy is obvious.

**FOCUSSED LIGHT.**—Last year I took the above premises on a ten years' lease, renewable at my option for fourteen years. The shopkeeper next door is now enlarging his premises by building out at the back. This new building, when finished, will stop off nearly all my side light from the north. I am told that, as my studio has been built over ten years—twelve, in fact—I can stop him from obstructing my light, unless he pays substantial compensation. I shall esteem it a great favour if you will be good enough to say how I stand in the matter. I. Cox.

**NO.** We are afraid—indeed, sure—you can do nothing in the matter but grin and bear it. Had the studio been built twenty years you could claim "ancient lights." Then you could have stopped the building if it did not leave you sufficient light to carry on your business. Nothing less than twenty years' obstructed light confers the claim of ancient lights.

**ON CARBON PRINT.**—I am sending you a carbon print which will see has a yellow stain in the middle, which seems to have come out after it was dry. It seems to be like a P.O.P. print that has begun to fade. I have never heard of carbon prints going like this before. Can you suggest the cause, as I have never heard of carbon prints fading in this way? The print, as you see, is on thick rough drawing-paper, and by single transfer process.—W. A. BENDER.

The cause of the yellowness is not far to seek. The bichromate was not washed out of the paper before the print was

dried. The stain was there, but probably you did not notice it while it was wet. It might easily be overlooked if the work was completed by artificial light. You must keep in mind that prints on thick paper require a long immersion in the alum solution to soak out the unaltered bichromate, particularly if they are left mounted upon it for a long time before they are developed, as then the bichromate penetrates deeply into the paper.

**G. P. A. (Bristol).**—"A Treatise on Photogravure." By Herbert Dennison. 4s. 6d.

**CARBON PRINTING, ETC.**—Should esteem it a favour if you will give me a formula for a spirit-sensitising bath for carbon tissue—preferably with pot. bichrom.—also stating time of immersion. Also will you kindly give address of the makers of a series of supplementary lenses used in conjunction with an ordinary lens (i.) to increase focal length, (ii.) to reduce focal length (for wide-angle work), (iii.) for portraiture, (iv.) for copying; priced, I believe, at 20s. set?—ARCHIE T. HANDFORD.

1. Spirit sensitiser is applied to carbon tissue by brushing it on, and not by immersion. With a solution of bichromate of potash less spirit can be used than with one of the bichromate of ammonia. The following answers well:—Bichromate of potash 6 parts, water 100 parts. When dissolved, add liquor ammonia till the solution looks quite pale. Then add methylated spirit 100 parts. This gives practically a 3 per cent. solution. The methylated spirit must be free from the mineral spirit. In place of the spirit, acetone may be used, if the ammoniacous salt be employed, then the ammonia can be omitted. The Autotype Company supply a spirit sensitiser which we believe is a secret preparation. It is cheap, and with it is supplied a suitable brush for its application. Its price is but 1s. a bottle, including the brush. We should think you could not do better than purchase that and save yourself the trouble of compounding it. You will find the tissue to dry much more quickly than with the home-made preparation. 2. Messrs. John J. Griffin and Sons, Kingsway, London.

**ENLARGEMENT BUSINESS.**—My friend and I are about to start a photographic enlargement business (not photography), but we have not decided as to whether to open a shop, or some premises in London and work for the trade. Should you, however, advise us to open a shop, could you give us an idea as to the best locality? Also what would be necessary to lay out for same? Your expert advice will greatly oblige.—ANXIOUS.

We cannot see that you will command any business by merely opening a shop. You must decide for yourselves whether you make your business for the trade and profession or for the amateur. If we may judge of your inexperience from your letter, we advise you to take some business of which you have greater knowledge.

**APPRENTICESHIP.**—Will you be good enough to tell me if an apprentice, after he has served his term, can legally set up in business for himself, or enter into partnership with another, close to his late master's premises, or in the same town, which is quite a small one?—MASTER.

Yes, he can, unless there was a stipulation in the indenture that he should not do so.

**AIR-BRUSH.**—Do you think if I purchased an air-brush I could teach myself to produce good work with it? I have a second-hand one offered me cheap, and I want to improve my position.—KATE

All will depend upon your artistic abilities. We would, however, say that you would save yourself much time by taking a few lessons from someone proficient in its use. We would also advise you to get someone who is familiar with the apparatus to see for you that it is in good working order, as second-hand ones are not invariably in a working condition.

**A COUNTRY ARTIST.**—If the finished enlargement, returned by your customer, shows discoloured marking within three months, you should certainly demand from the firm that supplied it that it should be replaced free of charge, or the money paid for it returned. We do not think you would be very successful in an action for damages for injury to your reputation; though one can well understand that, in a country place, it would suffer injury from supplying a picture for which a good price was

charged, and which had deteriorated in so short a time. We do not see that you can refuse to return the money to your customer, seeing that he has been supplied with a picture which is evidently in the early stages of fading. Possibly he will be satisfied by its replacement by another, with an assurance of greater permanence.

**J. H. WILCOX.**—Any of the manufacturers of carbon tissue will supply you with one of a very similar tint to the print you enclosed. We cannot say which of the firms supplied that with which it was actually made. Better write to the different makers and ask for their samples of tissues. From one or other of them you will be able to select the tint you require.

**STUDIO QUERY.**—I have a room 12 ft. long, 5 ft. wide. Do you consider this large enough to take full-length cabinets and C.D.V. photographs by electric light? If so, what focal length lens would you recommend; also what make electric lamp, what power, and where would you fix lamp or lamps so as to give the best result? If room is not large enough, what size room would you recommend? **ELECTRIC.**

The room is much too small to take full-length cabinet or C.D.V. portraits in either by electric or day light. There is no lens that will enable you to take full-length portraits cabinet size in so short a space. If you refer to the issue August 23 last, p. 635, you will find an article in which the best dimensions for a studio are given.

**BACKGROUND MAKERS.**—Will you kindly answer this in your columns:—1. Address of Rough and Caldwell, background makers. 2. Any other high-class background painters' addresses, not cheap quality ones.—**S. DRUNJEEBOY, Trimulgherry.**

1. Rough and Caldwell, 155, West 29th Street, New York, U.S.A. 2. Perberton and Co., Rishton, Blackburn; Turner and Co., Exchange Street, Blackburn; also others whose addresses appear in "B.J. Almanac."

**BROMIDE.**—Apply to the Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C.

**ARTIFICIAL LIGHT.**—Will you be kind enough to let me know the cheapest way I can take photographs at night, either full length or vignette, in a studio? I am not very well off, and should be greatly obliged if you will do so. I certainly cannot afford electric light, and I see in this week's "B.J." an article by Franz Novak. Also will you kindly say how to get the thorium nitrate, and how to arrange to burn it?—**GERTIE WATSON.**

The Tress Company supply a quite inexpensive arrangement for taking portraits by artificial light. Better apply to them at 42, Oxford Street, W.C., for a prospectus. Thorium nitrate may be had at most large chemists, but we should advise you to have nothing to do with the compounding of flashlight powder, as you probably know little of chemistry and the dangers incurred in making them.

**ENLARGEMENTS.**—1. Will you kindly inform me if I could obtain good results by exposing for enlarging purposes home-made bromide paper, wet (as soon as sensitised) with the surplus silver salts unwashed? 2. If so, will you kindly send me a formula for sensitising it? 3. I enlarge by artificial light, and use a weak illuminant. 4. A minimum of gelatine would be necessary (if any), as I want the image to remain sunk into the paper, and not "floating" on it as is the case with the commercial papers.—**A. G. C.**

1. We are sure that you would not find it practicable to prepare your own bromide paper, even by the modified process which you suggest. 2. A better plan would be to use what is known as the "Solar" process, formulae for which have already been given in our columns, and appear also in the current "Almanac," pp. 816 and 821. 3. For working by the "Solar" process you would want a powerful arc light for the enlarging lantern. 4. Any bromide emulsion paper must of necessity contain more than sufficient gelatine to keep the image from the paper. What you suggest is not practicable, for a bromide emulsion, but may be done with any floating or sensitising method such as that we have suggested.

**COPYRIGHT.**—I enclose a print of my copyright photograph of the Carisbrooke Well-House. I also enclose a postcard in colours. This latter is said to be a copy of an original oil painting in the possession of the publishers. A comparison of number of

links in chain, position of glasses, the wheel in relation window behind, also the position of the donkey, show the picture and this coloured card are identical. I should be of your opinion as to this, and if you agree with me, would fact (if it is a fact) that the coloured card is a copy of original painting (the original painting being a copy of photograph) preclude me from taking successful action to restrain the sale and for damages.—**F. N. B.**

It makes no difference as regards infringement whether coloured copies be actually made from a print of yours or an infringing oil painting. If it is a "colourable imitation" it is still an infringement.

**COLOUR FILTERS, ETC.**—1. What preservatives and the amount same may I add to the gelatine in preparing colour filters something that will not injure nor change the absorption dyes? 2. How to make flexible colour filters. Gelatine (Nelson's No. 1 Photographic) is too hard and brittle. 3. Using Dr. Miethe's formula for "blue" printing as a base theory governs the proportions given?

1. Water dist. ....	150 c.c.s.
Potass. ferricyanide .....	4.5 gms.
2. Water dist. ....	150 c.c.s.
Ferric and am. cit. (green scales) .....	12.5 gms.

4. What effect would any change in these proportions have? **W. H. THOMPSON.**

1. A small proportion of pure carbolic acid may be used if the filters are coated with fresh-dyed gelatine solution at once cemented no preservative is necessary. 2. If a glycerine be added, brittleness in the gelatine will be avoided. A very small quantity will suffice with this gelatine. 3. Small variations in the proportions of the ferricyanide citrate will make practically no difference in the results. The formula is that most commonly used for a good blue print.

**WORKING-UP.**—Could you oblige me by stating the best instruction obtainable in working-up black and white, colour same, and also miniatures?—**H. WHITWELL.**

"Retouching Negatives and Working-up and Colour Photographs." By Robert Johnson (Marion and Co.) 2s.

**Q. S.**—*n* signifies molecule grammes weights; *n* signifies normal, as it is usually written in books of analytical chemistry. The meaning of / and // is "positive" and "negative" respectively. As to the books, those in Sir Wm. Ramsay's series are the Messrs. Longmans, the publishers, will send you a circular.

THE LATE MR. CHAPMAN, of Manchester, left estate valued at £31,850.

**THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—The annual meeting of members of the affiliated societies will be held at the New Regent Street (by courtesy of the Royal Photographic Society) on Friday evening, September 27, at seven o'clock, when the Executive Committee hope to have the pleasure of seeing a large number of members present. The exhibition of the Royal Photographic Society will be open to members. The 1907 prize lantern slide will be shown. Dr. Evershed, the Chairman of the Executive, will give a short address on the work of the affiliation. Admission will be on presentation of the red book, and the tickets contained therein will be available for the friends of members. Visitors will be able to obtain refreshments at the Gallery.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Exhibition of the Society of Colour Photographers opens at 8 of the "B.J." on Monday next, September 30.

Lumière Co. announce that they have "Autochrome" plates list sizes. (P. 741.)

Another patent in screen-plate colour photography has been d. The drying of plates and films, backgrounds in nega- dographic surveying are among other patents of the P. 737.)

Lumière "Autochrome" plates will probably lead to a d of the foreground shutter. (P. 726.)

Warner-Powrie Process.—Mr. A. J. Newton looks forward to d uses of the linear colour-screen plate in photo-engraving.

Remarkable telephoto work at forty magnifications has been Captain Owen Wheeler with a new high-power attachment d only a 16-in. extension of camera. (P. 728.)

Protest against the methods of the press photographer d in a northern newspaper. (P. 742.)

Draw attention to the tendency of decrease in weight of d and of increase in lenses. (P. 725.)

Further experience in the treatment of the evil effects of d on the hands figures in our correspondence columns.

New Patents Act, which comes into force in January next, is d on its highly protective character, to affect foreign manu- d of every kind. (P. 727.)

First portion of a review of the R.P.S. Exhibition commences d. 733.

Inclusion of our notice of the Photographic Salon appears d. 731.

## EX CATHEDRA.

### The Christmas Booklet.

Our receipt from a firm of printers, with special qualifications for looking after photographers' stationery, of a booklet intended to draw Christmas trade to the studio, is one of the reminders that but a few weeks separate the height of the winter season from the present warmth of September sunshine. Our brief review of the booklet in question will show how we regard it as a means of attracting the public towards the photographer when Christmas gifts are in process of selection, but it must also be remembered that such a reminder must reach the public at the right time, and must have been preceded by arrangements for carrying out its offers well and quickly. Otherwise the photographer cannot expect to benefit much from it. Among high and low the personal note which a photograph strikes among Christmas gifts is more in favour year by year, and it rests with the photographer to take judicious measures to profit by it.

\* \* \*

### The Society of Colour Photographers.

A first look round at the collection of colour prints and transparencies which will be opened to the public on Monday next at our offices under the auspices of the Society of Colour Photographers, is enough to show the great value of an exhibition in which examples of the current processes may be compared side by side. While the Society introduces to the actual inspection of the public the first examples of the new Warner-Powrie process to be shown in this country, it should experience an equal satisfaction in demonstrating the progress which its own members have made in the more difficult colour-processes on paper, as evidenced in the work of its honorary secretary, Mr. Henry J. Comley, and of Mr. William Gill, of Colchester. Moreover, as a considerable proportion of the 200 exhibits are by the new Lumière Autochrome process, it may be said on the whole, for the Society, that its maiden appearance before the public as a body of workers engaged and interested in the progress of colour photography is one which does it credit. The exhibition, to which admission is free on signing a visitors' book, should certainly provide a fair idea of the present status of colour photography.

\* \* \*

### Cameras and Lenses.

There has lately been an unfortunate tendency for manufacturers of cameras and manufacturers of lenses to progress in opposite directions. While high-class lenses have been increasing in aperture, and consequently in bulk and weight, cameras have tended to become lighter and more fragile, and less suited to carry heavy lenses. There are many half-plate lenses now on the market that cannot be used with any

advantage in the average half-plate camera, hence the purchaser of one of these generally expensive and always useful instruments finds himself let in for the cost of a new camera in addition to that of the lens. Some cameras represent the last word in fragility, and when used at their full extension it is difficult to find any long-focus lens that is sufficiently light to be serviceable. On the other hand, some modern lenses of quite moderate focal length that have passed through our hands have been so bulky and heavy that they could only be used on cameras of exceptionally rigid construction. Purchasers of new lenses will do well to consider these matters before buying, and we think, also, that camera makers would be well advised if they introduced some cheap, rigid cameras suited to heavy lenses. It so happens that, while most of the light and fragile cameras are extraordinarily cheap, those of a more rigid and more substantial make are usually rather expensive, though their construction is, if anything, more simple. Therefore, the economical photographer has some difficulty in securing that very desirable combination of a high-class lens with a strong, serviceable, cheap camera.

### Foreground Shutters.

Every now and again we have to hark back in the photographic world to things that we thought had become obsolete. The introduction of the Autochrome plate has taken us back to the old days of long exposures with the stand camera, and the fact that over-exposure of the sky gives us a sky of an impossible colour impels us to look around for foreground shutters, which articles are rarely seen nowadays. Of late the foreground shutter seems to have been entirely neglected. Possibly we have become accustomed to over-exposed skies, and our taste has become vitiated, so that we do not recognise the falsity of the tone-value; but we can very quickly see the falsity of the autochrome pink sky, so it is evident that "steps will have to be taken." The generality of so-called foreground shutters only give the required effect when used for brief exposures of less than one second, therefore they are not suited to our purpose. The blind shutter fitted to the front of the lens can be used as a slow foreground shutter if we slowly open it by pulling the cord and then let it slowly run back again. Our blind shutters are, however, now usually fitted behind the lens, and this very simple dodge is not available. It is true that one can manipulate the behind-lens blind shutter so as to give more exposure to the foreground than to the sky, but it is difficult to do it without shaking the camera, because one has to pull against the spring when it is nearly fully wound. Another old-fashioned method is to expose with the lens cap,

manipulating it so as to partly shield the sky, but requires skill and practice. Probably the shutter suited to our purpose is the old flap shutter, that is slowly or rapidly according to the pressure put on a pneumatic ball, and is closed by relaxing the ball. Shutters are seldom seen now, but they were a very variety, and, in view of our present necessity, they are worth reviving. Their construction is very simple, they are cheap; and they also have the advantage of acting as sky-shades as well as foreground shutters.

### Lens Mounts.

There is a matter in connection with lens mounts that manufacturers well give consideration to. Many modern lenses mounted that a filter screen cannot very conveniently be placed at the back of the lens. The flange is often the centre of the mount, and the result is that the lens projects so far into the camera as to be a hindrance to the way of the screen. Of course, a middle position for the flange is advantageous for very heavy lenses, or for those that are used in folding cameras, but the average lens of less than 8 in. focal length is both small and light, and, excepting for folding pocket cameras, a flange at the back of the mount is as convenient as one in the middle. We were much struck with the inconvenience of the flange only a few days ago. Having mounted a lens in a behind-lens roller blind shutter—which is an ideal screen mount, as the screen is well protected on both sides—we discovered that not a single lens could be brought into use without packing out the shutter to a very considerable extent. Previously to this we often noted the inconvenience of internally projecting lenses in the case of lens panels that slide into place. The panel cannot be drawn out for the purpose of changing to a different lens without first unscrewing the panel. Instead of being able to shift lens and panel together, we have to replace them by another lens attached to its panel, and then to deal with lenses and panels separately, and a very change is impossible. In the cases of lenses of popular types, we do not see why purchasers should not be given a little choice in the matter, or, if various types of mounts are objected to for commercial reasons, it would be easy to supply either a special flange or an adaptor which would convert the central flange into a rear one.

### Blisters on Bromides.

A letter from a correspondent writes that 703 attributes the blame for the appearance of blisters to the use of soft water. His supply being changed from hard to soft, numerous blisters appeared. On changing back again to the hard water, the blisters disappeared.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### SCREEN-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of photographic reference.

The ALMANAC for 1908 will appeal to photographers all over the world as a daily reference guide in practice. The standard matter and formulæ will be revised and added to where necessary, and, wherever practical features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the edition of the ALMANAC (25,000 copies) will again be in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end is earnestly esteemed by the publishers.

blisters ceased to appear. This is exactly what might be expected according to the theory we suggested in a recent paper. The purer the water used for washing the greater the chance of blisters if precautions are not taken. The sudden change from a strong hypo bath to pure water will be nearly certain to produce blisters in a paper liable to form them, hence the efficacy of dilute hypo or salt baths between the strong fixing bath and the water. All the same, there seem to be bromide papers on the market that do not blister even when treated in the most carelessly rough fashion. It is a difficult matter to produce a blister experimentally on some of them, hence we are forced to consider that the paper is at fault when blisters do appear suddenly. A change of paper is therefore the wisest course to adopt when blisters are a serious source of trouble.

### THE NEW PATENTS AND DESIGNS ACT.\*

DURING the last few days of the past Parliamentary session the Royal Assent was given to two new Acts with regard to patents—the one the Patents and Designs (Amendment) Act, 1907 (7 Edw. VII., c. 28), and the other the Patent and Designs Act, 1907 (7 Edw. VII., c. 29). These Acts, both of which have just been published on the same day, annul each other to a remarkable extent. The whole of the first-named Act is repealed by the other. It is a cause for surprise why the former, which contains some two-and-twenty pages, was issued at all, seeing that was repealed before it could have come into force.

There are, however, some points in the new Act, which becomes law on January 1 next year, that may be of interest to photographic inventors, not the least of which are the increased fees that will have to be paid by patentees. By the Act of 1883, the total fees payable for the full term of fourteen years was £154. In the Patents Rules, 1892, they were reduced to something under £100. According to the new Act they will amount, for the full term of fourteen years, to £155, or one pound more than under the 1883 Act. This, we imagine, will be no serious matter to photographic patentees, as very few photographic patents are kept alive for the full term. But when the patent is maintained for only six or seven years will make a considerable difference. By the 1892 Rules, after the fourth year the renewal fee for the next year was £5, for the next year £6, and the next £7. Now the renewal fees, after the fourth year, when they are paid annually, are the same as under the 1883 Act, namely, for the next five years £10 a year, the following five years £15 a year, and the remaining four years £20 a year. So it will be seen that under the 1892 rules a patent could be maintained for eight years for £30, whereas now it will cost £45.

In the former Acts the fee when applying for Provisional Protection was £1, and on lodging the complete specification £3. Thus for these payments a full patent was obtained for four years. It is the same now, except that on the sealing of the patent a further fee of £1 has to be paid. This is charged in respect of investigations leading to anticipations. If on investigation it is found that the invention has been wholly or in part anticipated, the Comptroller may refuse to grant the patent, or may order the applicant to make a reference to the complete specification as he thinks fit.

It must not be assumed that because a fee is charged for the investigation as to whether an invention has been anticipated that the sealing of the patent for it guarantees its validity, as it does not. Sub-section (6) of section (7) reads thus: "The investigations and reports required by

this section shall not be held in any way to guarantee the validity of any patent, and no liability shall be incurred by the Board of Trade or any officer thereof, by reason of, or in connection with, any such investigation or report, or any proceeding consequent thereon." The investigations made by the Patent Office, it may be mentioned, only apply to patents that have been already granted in the United Kingdom during the past fifty years. Thus, while it may happen that an invention for which a patent is applied may have been in use years ago but not patented, such anticipation would, of course, invalidate the patent. Or the invention may have been published prior to the patent, and that equally would render it invalid. Hence it will be seen that would-be photographic patentees should make investigations for themselves as to what has been done before, and not rely implicitly on the work of the Patent Office, which is merely a search as to what has been actually patented. Many inventions in photography have been published in the different journals, and patents subsequently obtained for substantially the same things. These, as a matter of course, would prove invalid if tested in a court of law. Under the original Act the time allowed for the lodging of the complete specification, after the provisional application had been made, was nine months; now it is but six months.

One of the most notable features in the new Act is that relating to the revocation of patents worked out of the United Kingdom. Hitherto it has been a practice with many foreign inventors to patent their inventions in this country, but with no intention of working them here. They manufacture abroad, and then send their products here for sale. By this means an undue monopoly has long existed. This has been notably the case with chemical preparations, such as the coal-tar colours, which were actually a British invention. The case of photographic chemicals may also be mentioned. The majority of the new developers, most of which are foreign inventions, are patented here; but they are manufactured in Germany and cannot be made in this country. In most foreign countries a patented invention must be worked in the country in which it is patented, and unless it is the patent lapses and is lost.

The new Act remedies this state of affairs, as seen by section 27 (sub-section 1), which is as follows:—"At any time not less than four years after the date of a patent and not less than one year after the passing of this Act, any person may apply to the Comptroller for the revocation of the patent on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom." One important clause in the Act is that exempting innocent infringers of a patent from liability for damages. A patentee shall not be entitled to recover any damages in respect of any infringement of a patent after the commencement of the Act from any defendant who proves that at the date of the infringement he was not aware, nor had reasonable means of making himself aware, of the existence of the patent, and the marking of an article with the word "Patent" or "Patented," or any word or words expressing or implying that a patent has been obtained for the article, stamped, engraved, impressed on, or otherwise applied to the article, shall not be deemed to constitute notice of the existence of the patent, unless the word or words are accompanied by the year and number of the patent. No one is allowed to use the term patent to any article or product which is not really patented, as by so doing he renders himself liable, as he did under the old Act, to a fine not exceeding £20.

It is noteworthy in connection with the Act, relating to designs, that anyone applying the term "registered"

\* The Patents and Designs Act, 1907. London: Wyman and Sons and Eyre and Spottiswoode. 5jd. The Act comes into force January 1, 1908.

to any design after the copyright in it has expired renders himself liable to a fine not exceeding £5. No mention is made in the Act with regard to the use of the word "patent" after the patent has expired. We all know that the term is used on many photographic articles the patents for which have long since expired—some lenses, to wit. It would seem, according to the Act, that this is not illegal, though in the case of designs the copyright in which has expired, it is illegal.

The grant of a patent under this Act does not authorise the patentee to use the Royal Arms, or to place them on

a patented article. The use of the Royal Arms for any purpose whatever without the King's authority renders the user liable to a penalty not exceeding £20. This is as it was under the old Act, and we allude to it specially because we know that some photographers are under the impression, if they have at some time or other supplied photographs to members of the Royal Family, or may have executed orders for them, that they are entitled to use the Royal Arms on their price lists, letter headings etc. Such is not the case; those who offend render themselves liable to the penalty.

## A NEW TELEPHOTO LENS.

For some time past I have been devoting close attention to telephotography, primarily with a view to rendering it of practical value for service purposes. In the spring of the present year I endeavoured to popularise the use of the extended hood

In common with all advanced workers in telephotography, I have found the long camera extension, formerly supposed to be necessary for high-power work, a great nuisance. It is true that very high magnifications are not commonly required. Still, and

A.1. Taken with 7-inch positive only. Note.—This and the telephotograph of the same subject are taken with the camera well within the room, to escape observation.

A.2. Telephotograph at about 8 magnifications. Taken (September 21) with a single lens of the negative combination.

A.3. Telephotograph at about 20 magnifications. Taken (September 21) with a double negative combination.

A.4. Telephotograph at about 40 magnifications. Taken (September 21) with a triple negative combination.

in connection with telephoto lenses, and on May 10 the "B.J." was good enough to reproduce some telephotographs obtained by me with the help of this appliance. The facility of working afforded by the long hood led to various experiments, one result of which is, I venture to think, of sufficient interest to justify my writing a few words on the subject.

enlargement of, say, 25 diameters may sometimes be useful, and in military work, at any rate, nothing much under 20 is of serious account. Even 20 magnifications with an ordinary "high-power" tele-negative needs an extension which, unless the camera be very solidly built, and a cumbersome tripod used, makes it extremely difficult to secure steadiness in the slightest breath of wind. Accordingly, it seemed desirable to me to con-

concentrate attention upon reducing the camera extension necessary to produce great enlargement, and when I mention that I have succeeded in obtaining nearly 60 magnifications with an ordinary square-form half-plate camera, having a total extension of about 16½ inches, I hope I may claim to have made a step in this direction.

The method I have adopted has the merit of extreme simplicity. I have been accustomed to use the highest power tele-negatives

B.1. Taken (September 21) with positive only.

could procure, as I found that, properly handled, these produced quite as good results as were obtainable with low-power lenses necessitating a longer camera extension. But the highest power tele-negatives on the market have a focus of over an inch, and these, with my half-plate camera, allowing for the inside projection of the tele-mount, gave at most only about 14 magnifications. Having a variety of tele-negatives, it occurred to me

B.2. Telephotograph at about 13 magnifications. Taken (September 21) with a single lens of the negative combination.

one day to use some of them in combination with a view to obtaining a still shorter focus. The result was so satisfactory that I went further and further, gradually selecting, eliminating, and correcting, until I eventually produced a practicable combination with a focus of only about a quarter of an inch, which I think must be regarded as the limit. Indeed, for all optical purposes, a much lower focus is sufficient. With a half-inch effective camera extension a half-inch tele-negative will give 29 magnifications, and this should satisfy any but the craziest after freakish results.

Having placed the matter commercially in the hands of Messrs. E. Staley and Co., of 19, Thavies Inn, I have latterly had the

benefit of their co-operation, and between us we have devised, and shall shortly have ready, a complete telephoto objective, the positive element of which will be the Euryplan, while the negative will be a convertible combination. Any of the lenses of the latter may be used singly, and in the standard set any degree of magnification up to about 30 diameters can be obtained with a double extension camera. Assuming the positive lens to have a focus of 7 inches, the foci obtainable by the half-plate worker with this instrument will range from 7 inches to about 18 feet! Naturally, the tele-negatives of this combination will work specially well with the Euryplan, but they will give thoroughly satisfactory results with almost any good lens having an aperture of not less than  $f/8$ .

Of course, the illumination when using a very high-power combination is not large, but that it is sufficient may be gauged from the fact that I have been able to focus sharply with a combination giving nearly 60 magnifications while using an  $f/8$  lens as the positive. Working at only 30 magnifications, with a 5.6 or 4.5 lens, there is plenty of light in all ordinary cases, especially if a few simple precautions, familiar to all telephotographers, are

B.3. Telephotograph at about 32 magnifications. Taken (September 21) with a triple negative combination.

observed, and a little patience exercised. In dealing with difficult subjects in a bad light it is convenient to be able to get the picture square on the plate in the first instance with the lowest-power lens of the combination. I need hardly add that the whole business of focussing at high magnifications is greatly simplified by the shortness of the camera extension, and the costly, though undeniably efficient, "Hook's Arm" is rendered superfluous.

Some will regard it as an advantage to be able to use a convertible combination in a rigid box-form camera. At any one extension an extraordinary range of magnifications can be secured by merely shifting the tele-negatives in a specially devised mount which enables a change to be effected in a few seconds.

Experiments have shown that, in spite of the multiplicity of reflecting surfaces, even a quadruple negative combination can be formed which is free from flare-spot. A tendency to distortion has been abated, and, in its final form, the Staley-Wheeler convertible telephoto lens will not only be an unquestionably convenient instrument, but will enter into friendly competition, as regards quality of results, with any of the excellent telephoto lenses now on the market.

OWEN WHEELER,

Captain, Reserve of Officers.

NOTE.—In every case these telephotographs were taken with an ordinary square-form half-plate camera, the effective extension (i.e., distance between negative lens and plate) being about 14 in. All have been taken (with the exception of A1) since the beginning of September, some in rather unfavourable weather. A 7 in. Euryplan Series III. was used as the positive in each case. The exposure in some cases was very incorrect; but I was frequently testing negative lenses, and combinations of lenses, of unknown foci, and accurate calculation was out of the question. Neither negatives nor prints have been touched.—O.W.

## SCREEN-PLATE COLOUR PHOTOGRAPHY BY THE WARNER-POWRIE PROCESS.

THE views of Dr. C. E. K. Mees and Mr. E. J. Wall on the latest development in colour-photography, known as the Warner-Powrie process, supplementing the descriptions published in the "B.J." of September 13, have continued the interest in the new process first awakened by the announcement of the peculiar facilities permitted by the linear form of screen-plate. The whole subject of screen-plate colour work is so new to the general body of photographers that it is not surprising that some difficulty is experienced in realising the methods involved in the Warner-Powrie system, and the simple form which they take in practice. A careful study of the letterpress and diagrams in our issue of the 13th should, however, supply a clear understanding of the respects in which the Warner-Powrie process is superior to others in which also the colour-screen is sandwiched between the glass plate and the emulsion film. One or two points arising from comments on the process which have already appeared in the newspapers may be mentioned at the risk of repeating what is clear to all but a few. It has been stated that the stages in development are much as in the Lumière, which is true as far as it goes, but overlooks the fact that in the Warner-Powrie system one colour-plate (negative or positive) can be copied from another, and therefore there is no need to adopt the roundabout method of reversal by solution of the negative image first obtained and redevelopment of the positive remainder. Apart from the numerous solutions and operations

required, that process demands a thin emulsion film, and therefore small latitude in exposure, whereas the ability to print from a colour-positive from a colour-negative calls for but the two operations of development and fixation, and confines the manipulation to procedures with which a photographer is well acquainted. The plate is thus able to carry an emulsion of the usual character, and the process thus gains in certainty in proportion to the latitude of the sensitive coating.

It will thus be understood that it is immaterial whether a negative is printed from a positive or vice-versa. The result of the triplicating process already described is the complementary in colours of one or the other, just as a negative may be printed from a positive transparency or vice-versa. Precisely the same conditions apply in preparing a set of colour-sensation continuous-tone positives or negatives from the single linear colour-negative or colour-positive. Here, again, the process is comparable with the printing from monochrome positives or negatives on glass. We print below some notes by Mr. A. J. Newton, Principal of the London County Council School of Photo-Engraving, Bolt Court, E.C., as to the relation of the Warner-Powrie system to photo-engraving, and shall follow it next week with a further article by one who has personally been in touch in America with Mr. Powrie's process at a stage in its history prior to the recent work which has systematised the manufacture of the screen-plates.

### THE WARNER-POWRIE SCREEN-PLATE FROM THE PHOTO-ENGRAVER'S POINT OF VIEW.

THE most remarkable feature, to my mind, about the Warner-Powrie process is the method of making the screen-plate. As described in the JOURNAL last week, two of the three coloured lines are made by exposing a bichromated colloid under another screen, the opaque lines of which are double the clear spaces, so that a narrow line of colloid is insolubilised, and after the remaining soluble colloid has been washed away by development in water, dyed (say with red), mordanted, and dried. The plate is then recoated, replaced under the screen, and shifted by means of a micrometer screw until the dyed lines are under the opaque lines. It then undergoes the same procedure as before, except that the colour with which the second line is stained will be different (green). The remaining space is now filled with the third colour, and the plate for the last printing does not need any registering under the negative-screen, for after re-coating it is simply exposed through the back, the two lines, red and green, already on the plate, serving as a negative, and preventing the colloid under them from becoming insoluble. After developing and dyeing with blue dye the screen-plate is complete.

The lines being 600 and upwards to the inch, whereas the finest ruled cross-line screens at present marketed are, I believe, 400 lines to the inch, it would at once occur to a photo-engraver to ask how Mr. Powrie obtained his original negative screen-plate of sufficient fineness. The reply is that Mr. Powrie makes black screens exactly like his colour screens, and simply goes on reducing the lines and spaces until he obtains the fineness he wishes. He informs me that he commenced with quite a coarse screen ruled in the usual way, but with great accuracy, and from it he has made with ease screens of a fineness equal to 1,600 lines to the inch of perfect uniformity. The diagram shows quite clearly how this can be done by exposing and developing the plate, blackening these lines by a ferro-tannic pro-

cess, and then recoating and replacing the plate in a different position. The second printing will give a screen of twice the fineness of the original, which is now replaced by the manufactured screen, and this is made to serve as a nega-

tive to obtain another screen in the same way of twice its fineness, and so on. I have handled black-line screens, both fine and coarse, made in this way, that for all practical purposes would serve as well as the ruled cross-line screen does for making

half-tone blocks, and their cost should be enormously cheaper, as, asserted, one man, by means of a suitable printing machine, can make many dozens of them a day. Of course, any angle and any pattern of line can be produced in this way, and any width of ruling, any relationship of white space to black line. If there is any advantage in the use of fine screens it should soon be possible for the photo-engraver to try them, though, precluding the difficulties of paper and printing machinery (which have been overcome in the case of using 200 to 400 line screens) there is no further trouble when using a finer screen, it must still be remembered that the finer the screen the flatter the result—because of the increasing number of black dots in even the whitest spaces—so that, once the obviousness of the dot is avoided, there is no advantage except for special subjects, in which great detail is required, in the use of finer screens. But screens of any ruling ought to be easy to make by this method, and therefore cheap to buy. Thus could be made the coloured cross-line screens suggested by Mr. F. E. Ives in his lectures at Bolt Court School in 1898 (*Technical Education Gazette*, January, 1899) as being a possible means of obtaining better gradation in making half-tone negatives. The manufacture of these screen-plates is essentially the same operation as the printing on to metal of every half-tone negative, and if Mr. Powrie has simplified and perfected it so much that one man can twice print a number of plates in one day, there should at least be something to show photo-engravers in the way of a printing-frame capable of rapid handling, to say nothing of any mechanical improvements in the operations of coating and development of the plates. It is certain that no such speed could possibly be attained if a frame with a multiplicity of screws such as time is wasted over in almost every process establishment to-day had been used.

With respect to the reproduction of colour blocks from these plates, it may at first sight be suggested that three screen-negatives could be made direct by simply focussing sharply the lines and placing red, green, and blue filters consecutively between the original coloured positive and a suitably sensitised plate. In fact, I lately read an article assuming this might

be done in the case of the Lumière Autochrome plates if it were not for the fineness of the coloured screens. But such a suggestion overlooks the fact that a half-tone negative requires dots (or lines) of different size but of the same opacity everywhere, while the silver deposit which gives the colour value to the Autochrome or Warner-Powrie plates is not of the same opacity, but differs all over the plate in exactly the same way as an ordinary continuous-tone negative, which, in fact, it is, except that it is laid upon a coloured screen. Further, in the case of the Powrie plate, too, it would be impossible, from the fact that the lines are parallel and very fine, to print these in exact register. A moiré pattern would be inevitable.

Nevertheless Mr. Powrie has by his ingenious method of printing developed the method so as to be of great value to the photo-engraver. By printing through a colour-filter, and angling the frame as shown in *THE BRITISH JOURNAL OF PHOTOGRAPHY* for September 13, he obtains three transparencies from the same negative, practically free from lines, corresponding to the red, green, and blue records, and from these, of course, the block-maker can proceed to make screen negatives in the usual way, as I have done. It is obvious that this offers great possibilities for certain work that is impossible with three exposures, and, if the plates can be made fast enough, there is no reason why we should not have snap-shots in colour reproduced by three-colour blocks in our magazines, and even in our newspapers! An advantage that the etcher would have in re-etching such coloured blocks is that it would be perfectly simple to supply him with a coloured print from the original negative as a guide almost as trustworthy as the original scene itself. It is not to be supposed that the plates will be used for ordinary copying of flat coloured originals, since the direct process is quicker and cheaper; but it may be pointed out that with good dyes in the lines of the plate, the emulsion properly adjusted for them, or for two of them and a compensatory filter for the blue, the ratio of exposure for the three colours will be automatically right.

A. J. NEWTON.

## THE PHOTOGRAPHIC SALON.

(Concluded from last issue.)

Mr. Reginald Craigie's portrait of "Mrs. Reginald Craigie," in red, and occupying the upper right corner only of the print, the edges of which cut off all the cranium, will remind visitors of the theatrical poster upon the boards of sandwichmen crowding outside the gallery. The face upon this poster is disposed in exactly the same way, and is in the same sanguine hue. It is no less artistic, and perhaps a little more arresting, than Mr. Craigie's photograph. His portrait of "Kenneth Grahame" is a sounder work in every respect. We like it extremely, but take exception to the lights of the face, which appear to us to be hard and white, and not sufficiently differentiated from those of the hat which have the same qualities. Presumably the works of Dr. Evershed are oil prints. "Sunlit Sails," idly hanging on what looks like a Dutch canal, do not seem to be very sunny after all. We should like to know how Dr. Evershed could treat them differently to represent a grey day. There is undoubtedly some sort of quality in this print, but there is little that convinces. "The Signal Box" and "The Dominant Power" please us more. Both these pictures have not only good quality, but a nice appreciation of the artistic aspect of commonplace things.

It is to be regretted that Mr. Arthur Marshall has fallen away from the standard of his fine architectural work last year. The three things he now exhibits are varied in style certainly, but not one of them show the serious effort and exquisite taste

that we had hoped for from him. The best is perhaps "The Pastoral," which can boast of a nice design, but "Under the Chestnuts" has not even so much to recommend it; indeed, we fail to find anything at all under the chestnuts but a clean-swept gravel road. We could forgive so bald and clumsy a selection if there were any attempt at a good effect. If there really be any here its results escape us. As for the hideous "Le Pêcheur," it offends our eye from all parts of the room. This horribly coarse dark face of a repulsive and aged Dutchman ought never to have been hung in the gallery. Its screaming white background only cuts its ugliness out the more distinctly. We had thought that Dutch for the sake of Dutch had sunk below the level of the Salon, having by now percolated through musical comedy and settled at last as a catchpenny upon the vulgar postcard.

We fail to see anything suggestive of "Spring" in S. Carter's archaic-looking arrangement of sparse leafage, which is more suggestive of Oriental embroidery. His "Self-Portrait" is spoiled by over-diffusion.

The colour of Mr. Yarnall Abbott's "Street in Rothenburg" is so abominably unpleasant that further scrutiny than the first glance at it is impossible. As to the "Effect of Sunlight, Nurnberg," we cannot see it, repulsed as we are by the crude and twangy cast of the blue that only make both attempts ghastly. Mr. Abbott prices these precious things at fifteen and ten guineas respectively. Not that it matters, we expect, but the

comparison is a little obvious between these figures and the modest ones, twos, and threes that would purchase many of the best things here.

On the other hand, Mr. Cavendish Morton, a compatriot of the last-named gentleman, wants but two guineas for one of his dashing portraits of ladies. We admit that this particular one, with twelve words to its title, is not the best of the three, and that the others are unpriced, but they are all similar in style and size. "The White Plume" is an extremely captivating work, surpassed perhaps by the very chic "Portrait" which is an essay in contrast. A lady in black with a large hat and a white front stands at the wall of a vestibule which is light in colour and charmingly illuminated. A small antique clock upon a bracket comes in the scheme admirably. The whole thing is both delicate and strong.

A capital portrait of Holman Hunt in the robes of his degree is from Mr. Frank Hollyer, whose two sons also contribute a picture apiece. That of Mr. Frederick T. is entitled "Study," and "November," a print in two colours, is the work of Mr. Arthur. We congratulate the talented triumvirate of Pembroke Square.

"Expectation," "A Find," and "Such a Thirst" are tripartites with a variation, by Mrs. Carine Cadby. That we should be favoured with chicks and an egg is at least a welcome change, but surely one of these pretty things would have been enough in a gallery where space is denied to such quantities of more serious work. Mrs. Cadby's "Sand Grasses," a few black strokes on a white paper, shares the merits of her husband's "Snow Shadows." This happy pair certainly do set their reputations upon easy terms!

It is positively refreshing to turn to so noble a work as Mr. George Davidson's "Harlech," in our opinion one of the finest pictures in the exhibition. Instinct with style and dignity, it must come as a surprise to many who are unacquainted with Mr. Davidson's earlier triumphs, and misjudge his capability by the essays in diffusion which have represented him in the Salon for some years past.

A first-rate study of geese and ganders called "Sunlight" comes from Mr. W. Thomas, who has caught all the beauty that these birds, more than any others, seem to possess when strongly lit by the sun.

"Through the Pines" has a "mood," and shows the feelings that we expect from its author, Mr. J. C. Warburg, whilst a nice romantic feeling imbues Mr. J. M. Whitehead's "Moonrise," although the clouds appear to be tinkered.

A portrait bearing the name of Furley Lewis is, of course, much too artistic to be retouched into flattery, and for this reason we are made to note the flight of time as evinced in the features of "Walter Crane, Esq.," since the days when he was more in the public eye, and would have scorned to be called esquire.

"Sunlight in an Old Oak Doorway" and "In Westminster Abbey" are two excellent technical essays by S. G. Kimber. What and where are the claims to artistic photography in the gloomy "Place St. Remi, Dieppe," by Harold Jacob, puzzles us to see, but we readily grant them in the case of "An Impression of Glendalough," where the mountain towers over the tarn, and where the lighting is so impressive and the whole so dignified.

Herr Ernst Müller's four contributions are all good and interesting, the most romantic being "Das Tote Mar," whatever that may mean. But for a little monotony of tone, David Blount's "Trees in Shadow" are a good try for the picturesque. So also is "The Glowing West," etc., by Edgar Simpson, who has, however, made the water too dark for the sky.

The fullest congratulations are due to Mrs. Barton in having so cleverly posed "The Silken Gown," the light and shade upon the folds of which make an efficient and good subject.

"The Lighthouse," by W. Clark Pettigrew, a new name to us, is very good in many ways, but the sky is a little uncon-

vincing. We shall look forward to more work by this amateur. J. Dudley Johnston's "Sunlit Street in Berne" is a capital thing in most respects, but we cannot see how a tinting of colour only—blue—can be thought to enhance its effect.

### The French Salon—Oil Prints.

We have now dealt as fully as we are able with the British section, and there still remain the prints which are separately hung upon screens. These works, we are informed, were selected in Paris by the French committee. A considerable number of these pictures are by the oil process, and there appear to be few, if any, which do not owe their charm and quality to some method of control in printing.

The colouring is obtrusive in "Etude de Tête," by G. Gimé, but the play of reflected light on the face more than redeems this fault. His "Madame la Pluie" and "Mamzelle la Neige" are capital impressions of street life, though they are lacking in air. The works of P. Dubreuil have pleased us more on former occasions. The best of these here is, we think, "Portrait du Peintre B." This is a fine and vigorous thing. The painter, who is taking up the paint from a palette, is doubt short of sight, and his consequent action lends intensity to the pose. "Temps d'Hiver" strikes us as being too diffuse.

An extraordinarily vigorous and strong print is the "Portrait of Mr. B.," by P. de Singly, whose "L'Entrée du Village" should not be missed.

Of M. Puyo's works we have nothing but praise. His skill and facile manipulation never loses delicacy and refinement, no matter what he has in hand. "Dorine," which we are glad to see here, having already seen its reproduction, is a good example of his touch, and though quite bold and fearless, is the same time precise and well-directed. "Dans le Parc" we have marked as an excellent thing. In "Givre Matinal" we have our doubts as to the true relation in tone of the sky and ground. A lady resting on a sofa, "Après la Pose," is quite charming. In this there is a suggestion of the stippled effect of drawings of a past day. We do not affirm that the print so treated; perhaps the equal and sweetly graduated ink upon slightly grained paper alone suggests the effect.

M. Demachy shows five works in oil all of which are clever. We prefer the "Old House at Ploermel." It is simple and dignified, and full of quality. In his "Portrait of a Young Girl" M. Demachy gives us the impression of having overlaboured his print. We think cleaner spaces of tone would have still further improved this charming study. "Rouen" is full of beauties, and, to our minds, would have been even more interesting if the great distant towers had been less nebulous. "Autumn Mists" and "Le Louvre" are the remaining prints by this enthusiastic worker of the oil process. They call for no critical remark beyond a note of appreciation.

G. Maury shows extremely artistic work. He evidently understands accents and values, as witness his "Retour de Pêche" and his lively "Marché." "Brume et Neige" displays obvious

Mlle. Laguarde has a very captivating touch. It is not much to say that her "Femme aux Estampes" is the most precise and charming thing in the room of its kind. "May," a vignetted head, is not free of the taint of the chocolate box, but we admit its grace. Her print which shows most of the indispensable thing called "quality," is "La Maison de Fume."

The street scenes of A. Hachette are all instinct with truth of effect and pictorial feeling—the sunny and convincing "Soleil Pont Alexandre III," the "Port du Havre," and the "Pont de Honfleur." The latter is particularly broad and of fine design, and its grey quality is very winning. Why does the gentleman soil his prints with an impression from a rubber stamp? If the "Coin d'Annecy," by R. Michau, is an oil, heartily congratulate its author upon his use of the medium.

softness and crispness are delightful; but is not the shadow brown upon the surface of the water from the buildings too distinctly in evidence? Of "Pâturages," so rich and dignified, have become quite enamoured. "Petite Crique," by Ch. Mahéo, looks like a cleverly touched water-colour.

We have by no means dwelt upon all that pleases us in this delightful section of the exhibition. To it the Salon must owe much of the credit that is forthcoming, and we doubt the wisdom of the executive in keeping apart from their own works of such sincere and artistic effort.

## THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

[The formal opening of the Royal Photographic Society's Exhibition on Thursday in last week having now given the public the opportunity of visiting this large and representative collection of photographs, we may review in detail the many exhibits upon the walls, only the briefest survey of which it was possible to make between the press view and the publication of last week's *BRITISH JOURNAL*. The pictorial section of the Royal is this year an advance in the quieter qualities, which show a more careful study on the part of photographers, and tend to the exclusion of work which secures one's first exclamations, but does not improve on acquaintance. The West Gallery certainly contains a greater number of photographs worthy of study than we can now point to, or are likely to be able to do so during the exhibition season, and we must therefore deal at a fitting length with this portion of the exhibition.]

### THE PICTORIAL SECTION.

In our last issue we made allusion to several of the pictures at the new Gallery that might be said to stand out from the rest as particularly good. It must not be thought, however, that all else is markedly inferior. This year, more than usually, the visitor will find it difficult to parcel off the works into good, bad, and indifferent; for the more one looks at them the more they seem to be worthy to take a higher rank than a first glance allots them. We ourselves must read guilty to an oversight in not including in our select list the charming landscape (No. 290) by Mrs. M. E. A. Powles, entitled "Our Lady of Amiens," and the least we can do now is to testify to the first place in this review to its fine qualities. Its silvery tendence of colour eluded our too hurried glance. The cathedral is a misty distance, at its feet nestles the town, a band in stronger tone, full of suggested detail and admirable breadth. In front, on the banks of the river, thin sparse trees rise up as an open screen of scenery before the view, and the whole is reflected in the placid stream that runs across the foreground. The selection shows a fine taste, which is also borne out by the treatment of the print.

A large number of photographers appear to be obsessed with their ideas nowadays. So far as we have discovered yet, the colours limited by one process or another into printing processes—we do not allude to photographed colour—have been nothing short of dominant. In what way can two bald colours be used in a printing process to a true impression of nature, without upsetting the tradition and convention of monochrome to which the world has been accustomed since the invention of any sort of printing? How can a blue sky, or red on a face, or green in a field give, by any manner means, the very merest impression of a colour scheme, to say nothing of literal natural colour? If photographers who blindly rush to this pitfall imagine that they are doing decorative work allied to posters, show-cards, or stencilling, they had better learn as soon as possible the fundamental difference between conventions of that sort and landscape photographs. Sensations of colour in a monochrome are received through the language of tone and effect; to insert a trace of actual colour is to start the thing off upon a different line entirely, and from an artistic standpoint to damn hopelessly the work. Such a grating discord one would think only possible to the minds of infants and savages, with whom artistic logic is a book unopened.

The green and blue in Miss Hildegard Oesterreich's "Am Waldrand" (No. 3) is but barbaric. Without it her scheme of light amongst fir trees and a fence might have been a beautiful thing. Similarly the "Portrait of Dr. Bachmann" (No. 5), by Dr. A. Edenig, of whom we had better hopes, is positively no help. Otherwise the pose of the artist at the easel and the naïve strength of the design would have put this work among the few best. His "Farbenspiel" (No. 14), being nothing but chestnut leaves and what we must accept for a sky, is a little less objectionable for the reason that its *motif* is so bald as to creep in, by backstairs, to the domain of decoration. But, however successful his matching of natural colour may be, it has nothing whatever to do with photography when it is said. The Baron Imre de Vay Féll sends a "Lake" (No. 20) which, in spite of its particularly nice feeling, suggests by its colours a sort of aerograph tinting rather than any impression of nature.

#### The Girls and the Children.

Marg. Schürgast sends a "Jünges Mädchen" (No. 13) of the

sweet and simple type. She is very charming, and we much admire the treatment of her arms and hands, which hold the book so prettily. Her expression is most captivatingly caught. "At the Window" (No. 17), by Arthur Marshall, shows another of the genus, this time Dutch presumably. The pose is quite happily managed. We should have liked the picture even better had its effect of light been rather less hard and "edgy." Mrs. Barton sends "Flora MacLeod" (No. 55), a damsel whom we have met often before in photographic haunts. Her rather thick lips and rounded face give her a very youthful charm. There is nothing to be said against the attractiveness of "The Geisha" (No. 87), whom the Misses W. and G. Parrish have introduced between them; but as to the lantern she holds we can only express surprise that the Hanging Committee should have admitted so obvious a "fake" as the lighted candle presents outside the lantern to all appearance, and throwing not the slightest glow of illumination upon the figure. On the other hand, the truthful aspect of E. G. Boon's two little girls, who, being "First Arrivals" (No. 103), draw back a curtain timorously so as to peep into the drawing-room before entering, makes a capital subject, because it violates nothing of the possibilities of the action it depicts. Mrs. Barton's "Fates" (No. 130) attempts something rather in the manner of a well-known American maker of composite pictures. Her little girls are nicely posed and effectively dressed, though not fittingly in classic garb. In very suppressed tones, the shimmer and folds of the draperies are marked out with too much violence to please us. S. Elwin Neame, who made a good hit with a decoratively posed and draped young lady last year, repeats his success by another print (No. 135) of the same subject from a different point of view. It is rather early in a career to specialise to this extent. We trust he will find a new idea during the next twelvemonth. A demure little maiden "Studying the Nude" (No. 170), as exemplified in a small indiarubber doll, has taken most people by storm, because of the prettiness and easy possibility of the subject. This success is due to John Brown. "Peatella" (No. 193) has been capably posed by E. Ward-Thompson. She sits upon a chair in a sort of crofter's cabin and leans forward over her knees. Good lines result from this action as well as a capital scheme of lighting upon the folds of her dress, which is short enough to display her well-shaped limbs. It had been well if the photographer had given us her feet also. The colour of the print is, as usual with Mr. Ward-Thompson's work, highly pleasing. Still another by Mrs. Barton is a clever and taking subject called "The Lace Maker" (No. 234). A handsome young girl sits at a window making pillow-lace, her head relieved against the diffused light transmitted by the curtain. The style, design and management of this piece is, we think, an advance upon Mrs. Barton's already fine compositions, which hitherto have not seriously embraced effects of lighting. Recalling strongly a picture very popular in our youth, Mr. T. Lee Syms gives us two children in church listening to "The Sermon" (No. 249). The girl is fighting with boredom, whilst her little brother sleeps. It is quite well done in every respect. Another reminiscence is of the old Italian, Francesca, which comes of the beautiful profile sent by Anny Heimann, who calls it "Nähendes Mädchen" (No. 300). The neck of the girl and her general bearing is very sweet. Four little Dutch peasants quaintly sitting upon a sandbank constitute E. T. Holding's "Company of Angels" (No. 299). "Mother's Veil" (No. 266) is a

vignette of a pretty child's head and shoulder. We like it best of all Mr. Holding's works this year. It is fresh and strong and highly artistic in treatment. His more ambitious picture, "The New Piece" (No. 72), two children seated at the piano, which we now begin to think of as an old favourite, is by no means so good as some earlier piano pieces. We are disposed to think the shading down a little too obvious. The music is in a very bad light for practical purposes, and the relief of the heads against the wall is somewhat harshly marked. Apart from this, the work has all the charm of its author's style. Why did he not trim off some of the top margin? Count von Glöden's "Sehnsucht" (No. 48), a pretty tilted profile of a young girl, scarcely represents longing to our mind. Two very pretty heads of children, which Arthur Marshall calls "Sisters" (No. 69) should not escape notice. They are very tastefully mounted in a large grey circular mount.

### The Ladies.

A woman's head, life-size, and of exceptionally fine treatment, is by Dr. C. F. Grindrod, who calls it "Beyond." The abstraction in the expression is perhaps sufficient excuse for the rather elusive meaning of the title. "Lady K." (No. 35) is a pleasing portrait by Lette-Verein, whose works are new to this country. He sends from Berlin. From Hamburg, Rudolf Dührkoop forwards a splendid "Portrait of an Old Lady" (No. 174). The calm air and introspective aspect helps much the dignity of the design. She sits upon a settle against a wall whereon picture frames make good but pronounced decorative spots. Although the pose is a reversal of that of Whistler's "Mother," the idea and treatment readily suggests that masterpiece. In one respect Herr Dührkoop's posing is to be preferred, since he does not violate probability as did Whistler by setting his sitter in a parallel direction with the run of the wall, without any apparent object for such oddity on the part of an old lady. "Le Vase de Cuivre" (No. 178) is the very antithesis of the last, as French so often is of German. This lively and animated print by Pierre Dubreuil is light in tone, with a *motif* and arrangement of strenuous movement. The subject is a young lady issuing from a curtained doorway and holding a copper vase, whilst one arm is stretched up against the wall. We scarcely think her action is explained; but perhaps we are not expected to worry about that. The figure makes fine lines, and the print has fine quality and is decidedly arresting. Another study of action is Anny Heimann's "Tänzerin" (No. 188), which, though evidently the result of a rapid exposure, is so artistically balanced as to appear for the moment like a photograph of statuary. It thus avoids perfectly all the uglinesses of instantaneous work whilst it preserves the poetry of motion. Furley Lewis's "Colleen" (No. 274) is of the true Irish type with all its fascination. As usual, the print shows impeccable taste and skill, and the oval trimming is not unwelcome with such an arrangement of head and neck. Perfect work again is evident in "Im Hause" (No. 233) by Albert Gottheil. Certainly the two quiet housewives sitting so stolidly at needlework look as though they offered unusual facilities in the way of lengthy exposure; but nevertheless the picture is clever in the extreme, and partly so because of the true smack of German domesticity it so exactly conveys. Lastly, Mr. Holding's "Vase of Flowers" (No. 315) strikes a mean between the housewives and the dancers and the ladies perturbed by copper utensils, for his domestic elevates her arms only to place the vase upon a high window sill. A good line runs through the arrangement of the parts, which makes up a very pleasing study in light tones.

### Mere Men.

The male portraits are too numerous for exhaustive mention; but we will call attention to those which we think should be seen particularly, beginning with the very spirited "Portrait of the Etcher, Hermann Gattiker" (No. 39) and the much less satisfactory "Violinist—Arthur Hartmann" (No. 231), which though doubtless a perfect likeness and a wonderful piece of characterisation, is not an attractive subject. These are both by Herr Dührkoop. Lette-Verein's large portrait, called "Mr. E." (No. 49), has strength, certainly, though not so much the strength of conception as of pigment. This is not hard to come by, and we are disposed to think that the mere size and blackness of this work has led to its instalment in one of the places of honour. At the outset, we do not think it admirable to place an upright interest in the middle of an oblong shape just

for the sake of space of empty background telling as strength be it is black. As to the face itself, it seems lacking in the refinement of artistic vision which are obvious in the photographer's other work. An eminently pleasing group is sent by Miss Constance Ellis depicting "J. C. Warburg, Esq., and Son" (No. 60), who are seated before a large terrestrial globe the mysteries of which are being expounded the father to the son. The globe is admirably used both as a mass in the composition. The print is reticent in tone and in colour. "Portrait des Professor M." (No. 61), who is a painter, is an success due to the talented German lady, Mrs. Anny Heimann. head is a splendid piece of virile work. We are likewise pleased with Oscar H. Hardee's "Moses Melchior, Esq." (No. 130). F. T. Hollyer's first-rate "Professor Flinders Petrie" (No. 136) the "Portrait" (No. 142) by George Maus, so full of life character. "Sven Scholander" (No. 159) is one of the triumphs. Furley Lewis representing a Swedish gentleman holding a kite. Near by hangs "F. G. Stephens, P.R.B." (No. 162) by Hollyer. It may interest some to know that the three letters the sitter's name stand for Pre-Raphaelite Brotherhood. Stephens was one of the original seven, so many of whom are dead. This is a remarkably fine portrait of the picturesque artist with flowing hair and beard which, with the spectacles wears, are managed with a most masterly treatment—soft, yet firm. Next we come to another Furley Lewis, a double portrait of "Otto Hoppé and Marion Hoppé" (No. 166), tastefully posed as usual. His "Portrait of J. C. S. Mummery, Esq., F.R.P.S., President" (No. 217) is thought by some to be his highest achievement in this line of work. Without going quite so far we do not hesitate to add our tribute of praise to the peans that have greeted Mr. F. Lewis. Mr. Mummery wears his official air, albeit he smokes a pipe—combination of rare occasions: a cigar would have been to life. However, the likeness is good to "speaking" point in connection with this print we are asked to say that the information as to the price of duplicates, given in the catalogue, has crept in by accident. Naturally enough, no copies of this work are available for purchase. The "Portrait of H. Snowden-Ward, Esq." (No. 245), which E. O. Hoppé has made, is scarcely so spontaneous as could wish: the sitter has a look of posiness. More exciting, if beautiful, is Mr. Hoppé's top-hatted "meanister," whom he calls "An Auld Licht" (No. 175). We admit the cleverness of the photograph, though we must say that we do not hanker after it. Works in this class, good enough no doubt, interest us slightly and must therefore give way before pressure of space.

### Interiors with Figures.

Two unusually good works are sufficiently important to warrant this classification. They are "Morgensonne" (No. 164), by Albert Gottheil, and "Kartenspieler" (No. 267), by Otto Scharf. The first shows us the bedroom of a *mädchen* flooded with the morning sun, the brightness of which has tempted the occupant to pause in her one stocking up, one stocking down, whilst she looks out at the beginning of the morning. Her back is towards us, but the rays strike her form as they enter the casement. All the furniture of the room is clearly, but reticently, made out with the very perfection of values. Subject and execution are alike charming. Herr Scharf's interior is no less distinctly German. It shows a table in a *Bierhaus*, at which four men of various types sit playing cards, drinking, whilst a fifth looks on. Grouping and lighting are as to defy improvement. These merits, together with the charm in the heads, and the positive freedom from self-consciousness of the sitters, make a picture of absorbing interest. The only technical defect is a slight spherical aberration in the near objects. Lose of this and you have a modern Teniers or Ostade without the comicality. Of interiors without figures we have only to refer to E. Clappole's empty chamber called "Sunshine" (No. 23), a reflection of an old success.

### Figures in the Open.

Under this heading we include Leonard Missonne's beautiful "la Porte" (No. 129) and "En Passant" (No. 212), because although they could be fairly claimed by landscape, the figures form the part of their attractions. They are printed in a method and manner which should for ever silence the complaints of those who hold that a photograph should have no appearance but that of a photograph. We grant that in nine out of ten cases this law holds good; but this is the tenth case. The perfect touch of the

exactly resembles that of a clever chalk drawing—not a *bad* one, he it understood. In the face of such pleasure as it gives, rejection, upon principle, would be but hide-bound prejudice. Circumstances alter cases, and these are cases wherein we gladly congratulate the worker. "Sur la Porte" is like a Millet drawing. It is as full of sunshine as it can be, and the women who stand gossiping by the door are veritably in *plein air*. The other picture is of three little children who meet in a sunny road. Here again the truth of light and air go far to make this subject the favourite it is. Count von Gloeden shows a fine gallery of nude Italian youths, but they lack interest because the very qualities possessed by M. Missonne's works are

### THE PRIVATE VIEW AND CONVERSAZIONE.

[A numerous company assembled in the rooms of the New Gallery for conversazione, which is universally regarded as the one evening under the most agreeable social conditions, was just sufficiently well occasioned, and not so crowded as to be uncomfortable. To publish a of the people who are "in photography." Some few noble persons majority, as befitted the occasion, yielded themselves to the renewal of acquaintanceship which in many cases had been made at conversazione has led to us receiving a MS., which we cannot do

That the artistic talent of a photographer should be far-reaching enough to influence his wife's taste in dress, or the feminine circle in which he moves, is a pleasing little fiction one should, of course, boldly uphold, and with this idea firmly embedded in mind I entered the New Gallery for the soirée given by the Royal Photographic Society on Wednesday in last week. Was I to be doomed to disappointment?

A photographer may give his whole and undivided attention to his clients and their dress, in his daily round, and think that he has done his duty in his day and generation, but the refining influence of his profession should, of course, extend from the sacred portals of the studio to the innermost recesses of his wife's boudoir. My conclusion the next morning was that usually it does not; but I was more hopeful when I sallied forth: I had profound faith in the influence of the sterner sex. Why, after all, should it be really necessary to leave the pictures to look at the dresses? Would not the type of the photographer's work be indelibly impressed and reproduced in the personality of his women folk? Would there not be rich standard-brown carbon velvets, with subdued half-tones, and a costume such as the landscapes of Whitehead might inspire, touched with soft and white high-lights of trimming? Could I not see soft light clinging robes of the Romney period, with simple folds, long flowing graceful lines à la Neame, guiltless of trimming, beyond a floating scarf of chiffon, winding in diaphanous folds in graceful negligence round the figure? Would there not be others of the same kin in rich folds à la Liberty, puffed of sleeve, short of waist, and scant of material, yet fulfilling our poor weak notions of the canons of Art?

Yet, alas! woman is born to disappointment as the sparks fly upward! The modern creation of the latest fashion paper is far more in evidence than the individual expression in dress, of an artistic bent. The distinctive touch of a personality under artistic influences seemed sadly lacking, and I can only gather that the kimono bodice bore the seal of the photographer's approval in nine cases out of ten.

One most striking toilette in accordance with the artistic influence for which I searched was worn by a dark-complexioned girl, surely a disciple of Ruskin, gowned in deep cream tussore, with a bodice of modified pinafore type, the edge of the yoke ornamented with a hand-embroidered flowered pattern of violets, transparent elbow sleeves, and yoke of mauve chiffon. A quaint Eastern scarf of oriental colours completed a distinctive ensemble.

A good deal of black struck a slightly sombre note in the brilliantly-lighted reception room, but helped to relieve the lighter colours. I noticed particularly a black ringed and spotted design in white chiffon, trimmed with horizontal bands of black ribbon velvet, hemmed with black Chantilly lace, and a broader band of black velvet. Another dress of the much-worn black and white striped chiffon had a simple cross-over bodice, the fulness of which was gathered into a deep swathed belt of turquoise blue satin; bands and rosettes of the same trimming provided a finish to the elbow sleeves, and a long string of quaint blue beads gave another touch of the same hue.

A lovely powder-blue tissue, made also in kimono fashion, cut cir-

denied to them. The only contribution by Rudolf Eickemeyer, Junr., is a bright open-air scene of a coloured lady and her piccaninny, who asks, "Who's Dat?" (No. 165) at the retreating form of a stranger. It but poorly represents Mr. Eickemeyer's powers. "Taufgang" (No. 297) is a christening procession by Otto Scharf, also possessed of first rate out-door quality; but the chief interest of it lies, we think, in the humorous solemnity of the men and women who troop like sheep, but with bended heads and awful reverence, into the little church. Mrs. Ambrose Ralli sends a well-composed and impressive work of much quality, showing two peasant women seated upon a bank by the sea "Waiting for the Boats" (No. 312).

on the afternoon and evening of Wednesday in last week. The even- in the year when photographers and their friends are able to meet attended to leave not the slightest doubt as to the importance of the list of those present would be merely to enumerate the names of most were seen to be making a conscientious tour of the exhibits, but the opportunities for conversation, usually somewhat technical, and to the previous similar functions. A chance remark made to a lady at the better than give publicity to in this place.]

cular, and trimmed with a gathered band of the same material at the corsage and the hem of skirt, with sleeves of net and lace, was worn by a strikingly fair girl, whose broad deep band of blue ribbon velvet round her throat held together by a quaint gold clasp, gave it the artistic finish it needed. An olive complexioned girl, gowned in a peculiarly effective robe of palest pink chiffon, the bodice piped with velvet of a deeper rose shade, trimmed with filet lace, and hemmed with a deep rose velvet band, was conscientiously doing each room. Near her I noted a pale grey taffeta frock with broad yoke of steel sequins contrasting with the rich chestnut hair of the wearer. A very simple but graceful dress was worn by a dark girl of French blue chiffon de velours with a little pointed vest of écarlate, and a large black hat with long floating scarf of black Chantilly. Near her a crushed strawberry taffeta with numerous horizontal frills adorning both bodice and skirt and embroideries of blue and green ornamenting the corsage, whose owner, of a somewhat Eastern type, and whose hair, plainly parted in the centre and drawn back to a loose knot in the nape of the neck, gave one a vague sense of relief after the elaborate coiffure of the present day.

A tall and finely built lady of the Junoesque type was wearing a pale grey silk, filet net, elaborately trimmed with panels of pale grey silk, richly embroidered with touches of violet, graduated tucks to the skirt and the rich panels outlining the seams, struck a quiet, subdued, and refined note pleasant to dwell upon. With her passed the wearer of a black voile dress, relieved only by a handsome berthe of Maltese lace.

Amongst other black gowns a robe of fine black Chantilly lace over white chiffon, with transparent yoke and narrow belt of black sequins, was worn by a personality of some individuality. A slight fair girl, whose gown bespoke the exquisite finish of a Frenchwoman, was dressed in a semi-empire frock of black and white spotted silk, with narrow pipings of pale blue, yoke of cream filet lace, and cream applications of silk passementerie flecked with black, finished with pale grey tassels and a large black picture hat profusely adorned with white feathers and pale pink roses. With her was her sister, in a rich cream lace robe over taffeta piped with old rose. Near them was a tall distinguished-looking girl of the Gibson type, in a mauve taffeta shot with brown, the excellence of cut and combination proving another example of modern and up-to-date dress, rather than a follower of an artistic cult.

A dress of painted chiffon trimmed with creamy net and lace and a rich deep brown velvet robe, with fichus formed of alternate bands of lace and velvet, would perhaps help to bear out my opening statements, and give support to a rapidly weakening faith in the influence of the stronger sex.

I was disappointed in my hopes, for the few harmonious toilettes I have mentioned were but few among the autochromic clash of colours which attired but did not adorn many a feminine figure. My question as to the art influence of the photographer had been answered in a chilling negative. Assuming the art feeling to be his, it should surely be possible for the photographer to give it domestic expression. "There must be some way of managing 'em," exclaimed a Henry-Arthur-Jones husband. Is the method still as much the ignis-fatuus as colour photography?

## THE GENESIS OF A MODERN LENS.

[The conclusion of a short series of articles expounding, in popular language, the processes of the factory and laboratory by which a modern anastigmat lens reaches its state of perfection, is reached in this present article by Herr L. Bünker, from the "Central Zeitung für Optik." The series, it is hoped, has shown the enormous care and equipment.—Eds. "B.J."]

ASSUMING that all the calculations are satisfactory, the first thing to be done is to make a trial lens. As a rule, a short focus one is chosen. The mathematician gives the exact construction data, that is, the radii and thicknesses of the individual lenses, and the first thing to do is to prepare test glasses for each radius. These play a most important rôle in the practical manufacture of a photographic lens, and cannot be dispensed with, as they give accurate control over the radii. After two brass patterns have been made to the given radii—these are concave and convex segments of circles of required radii, which are used for controlling that of the rough lenses—a pair of test glasses are made out of thick plate-glass for each radius, one concave and the other convex, and are worked to the patterns with various sized emery up to the finest grade. Then the patterns are discarded and a spherometer employed. This instrument is extremely precise, and enables one to control the radii easily to 1-10000 millimetre (= 250000 inch). When the test glasses are satisfactory they are polished, so that the one fits accurately into the other. There are two faults which may occur in making these test glasses. The one is variation from the spherical form, which can be easily controlled by the test glasses themselves through the formation of the so-called Newton's rings. The extremely thin film of air enclosed between two glasses shows by transmitted and reflected light colour phenomena, which appear, according to the degree of accuracy attained, in broad or narrow concentric colour rings, which finally fade into white, when the two surfaces accurately fit. Variations from the spherical form will then show themselves as colour rings. By the other fault is meant a variation from the desired radius, and this is shown by the spherometer. A good pair of test glasses, when placed together, must make coloured rings disappear, and the spherometer must show the exact radii.

The test glasses are only used to control the polishing of each individual lens surface, as, by placing them together, one can at once tell whether the necessary exactness in manufacture is attained, that is, whether the lens has actually the radii calculated by the mathematician. In order to give the lay reader an idea of the precision attainable by this method, it may be mentioned that an error of 1-20000 millimetre (= 1.500000 inch) can be easily determined. That the placing together of the finely polished lens surfaces and the test glasses must be done with the greatest care and only when they are absolutely clean is obvious, for a grain of dust between them may ruin the lens surface. Fraunhofer was the first to use test glasses.

Let us return to our test lens, and as this is of little interest we will assume it finished. It is then submitted to a very vigorous testing. In most lens factories specially constructed apparatus is to be found, which gives absolutely perfect test results. If these are satisfactory the manufacture can be proceeded with.

Naturally there are several preliminary matters to be attended to; thus the radii for lenses of all foci have to be calculated, the brass pattern moulds, the grinding tools, and the test glasses made.

When one pictures the long tedious work of calculation, and, further, how much time and trouble the preliminary work requires before the actual manufacture is begun, it will gradually be borne in upon one that only the most careful manufacture, combined with the most exact calculation, can give the comparatively cheap price of the modern anastigmat.

As a rule, the whole stock of the required kinds of glass are purchased from the melters. This is done to avoid too frequent calculation of the lens. For, although the same ingredients are used for one and the same type of glass, the subsequent meltings have rarely the same optical constants, that is, the same characteristic refraction and dispersion. If this difference was large, which may happen to be the case, a complete recalculation of the whole lens is necessary.

The blocks obtained from the glass works are split up into pieces by diamond saws or wheels into convenient sizes for the single lenses. Then these pieces of glass go to the grinding-room, where, with white

river sand and special machines, they are worked up till they have the shape of the finished lens. After this they are taken in hand by the fine polisher, who works the two surfaces of each lens with emery of ever increasing fineness. The principal points to be observed are that each surface has its proper radius, and that it is free from scratches and holes, and also that the prescribed thickness is retained in the centre.

When this is done the surfaces are further polished, so that the reflected image can be seen in them, and then the lenses go to the center. On a lathe with horizontal spindle this man cements them on an accurately running pike or mandrel, directs the lens towards a contact lever, the point of which lies on the centre of the lens, and then cuts away the edges with a special arrangement till the lens has its destined diameter. The important point in this is that the glasses are running truly central after being cemented, and that after centring the optical axis coincides with the axis of the lens, which with convergent lenses is the thickest part, and with divergent lenses the thinnest.

After this the polisher receives the lenses thus prepared, and cements them to a corresponding dish, and then the polishing discs are moved by special machinery with regular movement. This is continued till the surfaces are absolutely clean and fit the test glasses accurately. If the test is satisfactory the lenses again go to the cementing room. Most lens systems are composed of several lenses cemented together. The cementing is effected with Canada balsam, which is rendered fluid by heat. The lenses, heated to the same temperature, are brought into contact and pressed together, so that an extremely thin film of cement remains between them. On a specially constructed apparatus, which is provided with an ether level, the two cemented lenses are adjusted, that is, shifted one on the other till the axes of the two lenses absolutely coincide. After the lenses have undergone another superficial test—the accurate test is applied to the finished lens—to see whether by accident a wrong glass has been used, they proceed to the mounting-room; the optical part of the work is done.

### Mounting the Lenses.

In the meantime the mounts have been finished in the rough, and the actual lens fittings are turned out of brass or copper on a lathe. The tube is also turned out, provided with a slit, and the iris or other diaphragm inserted. When the screws and flanges are finished it goes to the engraver.

Then the fitter of the lenses begins his work. This very delicate operation must be carried out with the greatest accuracy, as a badly set lens seldom gives good pictures. If the lenses have been previously set by the level by the center the work is comparatively simple, when the fitting has been well turned, and the objective consists of only two lenses. It is much more difficult when there are three lenses to the system. In this case it is the special work of the fitter to arrange the lenses in their cell, as the cementer can only adjust two lenses with his apparatus. There are several methods of fitting lenses, but for precise instruments the method of edging is preferred. On the rotating spindle of the lathe the cell is screwed. It is given a very fine edge, the lenses are placed in it, and the whole heated so as to slightly soften the cement between the lenses. With the straightening board or fork they are now adjusted, till a reflected image in the rotating surfaces is absolutely stationary. In this position the lenses are fastened in by spinning in the edge. When finished the mount is lacquered, and the complete lens goes to the studio for testing. The testing processes differ, but when the lens has passed these it is ready for the market.

This is practically the whole process of the genesis of a modern lens. Only those explanations have been given which will make clear to one and all that our modern anastigmats are instruments of precision and involve an enormous expenditure of care and time, and that they are well worth the price asked for them.

LUDWIG BÜNKER

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for patents were made between September 9 and 14 :—

**CAMERA STANDS.**—No. 20,057. Improvements in photographic camera stands. Thomas Percival Woolfe, 34, Upper Street, Islington, London.

**PRINTING FRAMES.**—No. 20,171. Improvements in or relating to photographic printing frames. John Samuel Irving, 18, Hertford Street, Coventry.

**COLOUR PHOTOGRAPHY.**—No. 20,329. Improvements in colour photography. Thomas Thorp, Knowsley Road, Whitefield, near Manchester.

**MATERIALS.**—No. 20,381. Manufacture of a new product from albumen. Peter Leuthardt-Thornton, 47, Lincoln's Inn Fields, London.

**PAPER.**—No. 20,382. Improvements in the treatment, or manufacture, and production, of paper and other materials for photographic purposes. Peter Leuthardt-Thornton, 47, Lincoln's Inn Fields, London.

**PAPER.**—No. 20,383. Improvements in the treatment, or manufacture, and production, of paper and other materials for photographic purposes. Peter Leuthardt-Thornton, 47, Lincoln's Inn Fields, London.

**COLOUR PHOTOGRAPHY.**—No. 20,384. Improvements in the manufacture of plates or films for colour photography. Edward Sanger-Shepherd, 4, South Street, Finsbury, London.

**PAPER.**—No. 20,472. Adhesive sensitised photographic printing paper. Louis Hyde, 30, Duke Street, Chester.

**CINEMATOGRAPHS.**—No. 20,490. Improved cinematograph pictures. Henry Otto Clausen, 116, High Holborn, London, for Mittet and Co., Norway.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOUR SCREEN PLATES.**—No. 19,652, 1906. The invention consists in a method of making colour screen plates for three-colour photography, etc. It consists in the manufacture of a taking screen, composed of oval or circular patches impressed on a transparent material in regular sequence and order for the first two colours and for the third colour the construction and use of a patch which is never the same shape as either of the other two, being, in fact, the remainder of the area of a surface after the other two are impressed upon it.

The following are two methods of carrying out the invention :—  
(1) A plate is made which by photographic or mechanical means gives a print in regular sequence and order of patches of circular or oval shape. With this plate an impression is made in a selected transparent colour on a transparent material as indicated in the drawing by the part marked A. The plate or material is then moved so that a second impression may be made in another selected colour, adjacent to the first as indicated in the drawing by B, the only necessity being that the patches shall not overlap.

Placing this two-colour screen with clear spaces between the colour patches in contact with a suitably sensitised transparent material on exposure to light, there is obtained a record only of the light that has passed through the clear space as indicated in the drawing by the part marked C. This plate or complement on being immersed in a dye bath of the third selected colour, will absorb the dye and become coloured in those portions which have been acted on by light. It is then cemented or otherwise placed in register with the first-named transparent material.

(2) Stripping or transfer paper is coated with a soft gelatine holding in suspension a silver haloid and when dry is printed on firstly in one of the three selected transparent colours, and after moving the position of the plate or paper as already referred to is printed in another of the three transparent colours. The

gelatine emulsion must be sensitised with a bichromate salt, either before or after coating or after printing the double series of patches. If done before, such printing must be carried out in non-actinic light. Whatever the procedure the sensitive paper bearing the double series of patches is then exposed for a sufficient time to light. The coating is now transferred by suitable

means to its transparent support, such as glass, gelatine, celluloid or the like, and the temporary support removed. The gelatine emulsion which is now uppermost is developed with warm water, and the soluble parts in front of the colour patches washed away, such development being rendered visible by means of the silver haloid, which also prevents too great a swelling of the gelatine. It is then fixed—i.e., the silver haloid removed by means of a bath of thiosulphate of soda in solution. The now clear gelatine between the colour patches is stained with the third selected colour by immersion in a dye bath.

The invention includes the adaptation of such screens to the construction of panchromatic plates, films, or the like, either by placing the screen in contact with the same or by making the screen to form a part of such plate, film, or the like. Clare Livingstone Finlay, 22, Marchmont Street, Russell Square, London, W.C.

**DRYING PLATES AND FILMS.**—No. 25,662, 1906. The invention relates to improvements in drying apparatus for photographic films, prints, etc., of the kind in which a network of wire cotton or other material is used for supporting the films. It consists of a fine meshed net woven from cotton. The net is gassed (that is passed through a flame to singe away the loose fibre and fluff) and stiffened with starch in the usual way and dried. It is cut into the size required, and the edges turned in and sewn, to prevent the edges carrying or breaking away. The net is boiled in many changes of water until all grease and other impurities are removed, and it is then hardened in a formalin bath and again washed in several changes of cold water and stretched upon a wooden frame, of any required size and shape, and held by means of small round-headed nails, which are not driven entirely home, so as to allow of the net being removed or replaced at will. All that is necessary is to take the prints, or films, directly from the water, after their washing is completed, and place them face downwards on the net, which may be suspended in any convenient place until the prints, or negatives, are dry, when they will strip away perfectly flat, and show no marks or stains from contact with net. The latter is always ready for use, but if by continued use or accident it becomes dirty or stained it may be removed from its frame, cleaned, and replaced. Benjamin Henry Williams, 12, Castle Street, Dudley.

**BACKGROUNDS IN NEGATIVES.**—No. 24,065, 1906. The invention relates to improvements in the method of obtaining a composite negative whereby a suitable foreground or background or both can be combined with a central figure or figures, and consists in

photographing the principal object and the chosen background and foreground on separate plates or films and in cutting out or removing portions of each negative film so obtained in order to build up a single composite negative. For this purpose it is necessary to employ plates or supports, the films of which can be readily removed and handled in order to transfer the cut out portions to the final support.

Having taken the two negatives the principal object is cut out from its film, following closely its outlines, and a corresponding part is cut out of the "background" negative, and the former is fitted into the cut out space of the latter, whereupon a compound negative is produced from the figure or principal object of one exposure inserted into a corresponding opening cut out in the negative of a selected background view. Obviously instead of both the foreground and background being taken on one plate or film two different negatives may be taken and the selected parts combined as above stated. The process can be simplified and cheapened by utilising for the background view not a photographic print, but a photo-mechanical print.

Although according to this process a background negative is required for each photograph, it is in practice not only better, but also considerably cheaper, because the comparatively more expensive plate for photographing the principal object can be utilised to the full extent, that is to say, up to the edge, whilst the much larger background is obtained cheaply by copying on a transfer film.

To obtain a composite negative according to the invention, the process is as follows:—

A negative, preferably on a transfer film, is taken of the principal object. A separate negative (or negatives) is taken of a selected background and foreground, also on a transfer film. The principal object is then cut out from the first negative, following more or less closely the outline of the object, and the film so cut out is then placed on or under the background negative and a corresponding part is cut out from the latter. The "object" film is then inserted in the opening thus made and the two part films combined in one support.

The photograph of the object can be taken with a completely black background, and foreground, so that on development all parts of the negative except the object will appear as perfect clear glass or film. It is, however, better to moisten gelatinised paper and to place it on the negative, whereupon it adheres to it. After drying, the film can be easily removed or comes off automatically with the paper without curling. The cutting out of the subject photographed must be effected, except the part surrounding the face, in accordance with its outlines on the plate photographed. The more carefully this be done, the better will be the result, but it is not absolutely necessary to keep to it strictly, more particularly if the tone of the edges of the photograph corresponds fairly well with the tone of the corresponding portions of the background.

The process according to this invention may be simplified in the following manner:—The film obtained by cutting out the object photographed on the transfer negative film, is secured (preferably by means of gelatine) to the corresponding portion of a well cleaned glass (or film) of the size which the finished picture is to have. This is preferably done either by means of previously made marks or over a tracing indicating the said portions and laid under the glass. Or the film from which the object has been cut may be placed under the glass and the object film in place over it on the glass. After drying, the film support is removed. Then, without paying any attention to the object, and without having cut out the corresponding portion from the background film or photo print, the latter is transferred to the glass plate (preferably by means of spirit varnish), so that the background film is simply situated over the object film. After drying, the background film support is softened by moistening and removed, then the glue or paste layer is first washed away by means of a sponge or the like with warm water. Then that part of the background situated only over the subject film, is removed or washed away by means of some substance (for instance turpentine) which dissolves the medium in which the background film is printed, and the negative can then be touched up in any desired manner. In place of photo-prints, other pic-

ture layers, obtained by copying or developing, may be employed in exactly the same manner as above described, if means for solution of the film layer are known; thus, for instance, gelatin layers (or "celloidin" paper) can be easily dissolved by acetate, acetic acid, ether alcohol, etc. Carl Pletzner, Mariahilferstrasse, Vienna.

**CLAMPING MECHANISM.**—No. 9,115, 1907. The invention relates to the design of a clamping tool, suitable for the front of a camera, etc., and permitting of such portion of a camera to be quickly and firmly secured. Louis Gandolfi, 752, Old Road, London, S.E.

**CINEMATOGRAPHS.**—No. 24,953, 1906. The invention consists in the design of a special form of safety shutter for cinematograph. Leo Kamm, 27, Powell Street, Goswell Road, London, E.C.

**PLATE-HOLDER ATTACHMENTS.**—No. 20,782, 1906. The invention relates to improvements in photographic plate-holder attachments of the type wherein continuous motion of one part in one direction brings the plate-holder in position for exposure. On the focus screen being simultaneously displaced, it withdraws the cut slide or shutter and enables the plate to be exposed, the plate holder and its guides being adjustable as a whole relatively to the camera back and so permitting more than one exposure to be made upon a single plate. Kodak Limited, 57-61, Clerkenwell Road, London, E.C.

**PHOTOGRAPHIC SURVEYING.**—No. 16,812, 1906. The first claim of the invention is:—A method for the utilisation of photography taken from balloons, kites, rockets, or similar elevated stations in order to produce correct plans or contour maps by photographic means, according to which differences of scale between the elements of the photograph and the horizontal line of the eye's view, due to the fact that when the photograph was taken the photographic plate was inclined to the horizontal plane, are eliminated by a photographic transformation of the picture to the horizontal plane; and the differences of scale between the elements of the horizontal line of the eye's view and the map to the fact that the bird's eye's view sees the plastic ground at a finite height, whilst the map shows the ground as if it were seen from an infinite height, are eliminated by alteration of the scale of each contour zone of the perspective picture to the scale of the orthographic projection on the basis of an exact top plane of the ground. Theodor Scheimpflug, 39, Sternwartstrasse, Vienna, Austria.

Complete specification open to public inspection before acceptance under the Patents Act, 1901:—

**PLATES.**—No. 19,889. Processes for producing pictures, photographs, printing plates, or the like. Boerner.

#### CATALOGUES AND TRADE NOTICES.

**MESSRS. C. A. STEINHEIL SOHNE**, of Munich, have issued an illustrated price list of their photographic lenses and accessories, a copy of which has been sent us through this firm's London agents, Messrs. A. E. Staley and Co. The list contains the latest particulars regarding the well known Steinheil "Unofocal" and "Orthostich" lenses, and also a description of the "Multo-Nettel" hand-camera, review of which will appear in our pages at an early date. Mr. Staley will be pleased to send a copy of the list to any of our readers on receipt of penny stamp to cover postage.

**"AUTOCHROME" PLATES.**—We learn, at the moment of going to press, that Messrs. Adams and Co., of 24, Charing Cross Road, have obtained a new and very large stock of "Autochrome" plates.

**HACKNEY PHOTOGRAPHIC SOCIETY.**—The annual exhibition was held at the King's Hall, Hackney Baths, from November 6 to 12 inclusive, the judges being Messrs. H. W. Bennett, A. H. Blake, and Furley Lewis. There will be six open classes, and bronze statuettes will be placed at the disposal of the judges for award in each. Silvered statuettes are also offered for the best picture in the open and members' classes respectively, together with bronze plaques for the best trade exhibit and the most useful photographic negatives. Entries close October 19, and entry forms and full particulars may now be obtained from the hon. secretary, Mr. Walter Selby, Paragon Road, Hackney, N.E.

## New Materials.

ox "Vigorous Glossy" Postcards. Sold by John J. Griffin and Sons, Ltd., Kingsway, London. The new brand of the ever-popular "Velox" has just been issued by Griffin in order to provide for the wants of those who want a postcard of glossy surface, possessing also the necessary for in printing. This combination of qualities, so far as our experience of the new brand goes, is most satisfactorily obtained in the "Vigorous Glossy," which, with the normal metol-hydrozone developer, gives prints of great strength and purity. Despite its glossy surface, the new card shows very little tendency to surface-scum, but works in a remarkably clean manner, and calls for the minimum of trouble in the way of securing clean, brilliant prints. The "Vigorous Glossy" Velox postcards are supplied in packets of eighteen with mask, for 1s., or in packets of 144 for 6d.

"What Shall I Give?" Issued by Walter Pearce and Co., St. George's Press, Brentford.

Means of drawing business to the studio should surely rank among the most essential "materials" of a photographer, and for that reason we may justify a detailed reference under the above heading to a little booklet prepared by Messrs. Walter Pearce and Co., specially for the use of professional photographers intent on securing the advantage possible from the Christmas season. The booklet, which is entitled "What Shall I Give?" arrests attention as much by its matter—the problem of present-giving—as by its very attractive and dainty get-up. In a few words, it introduces the theme of a photograph as an acceptable Christmas gift, and from its richness of pink and gold impressed on a finely figured paper, conveys an idea of the photographer's taste which it is impossible to obtain in a local printer, however well provided he may be with types and inks. Messrs. Pearce supply the booklet exclusively to one photographer in a town, and we cannot suggest any better or surer means of stimulating Christmas trade than its judicious distribution among a selected number of possible patrons. The booklet course provides for the photographer's own announcements, in addition to which Messrs. Pearce will be glad to be consulted as to who know something of the best form which such announcements should take.

Mounts for Photograph Decoration. Sold by Kodak, Ltd., Clerkenwell Road, London, E.C.

The use of photography in home decoration has been written upon before and over again in the pages of our amateur contemporaries,

of being applied largely in the adornment of articles of furniture is most certainly the case, but we cannot recollect that any pieces of furniture have been manufactured specially for the incorporation with them of a photograph. This gap, however, has been filled by the Kodak Company, who, with great originality and good taste, have designed pretty nearly a dozen articles which are extremely well fitted for the reception of photographs, therewith form a decorative scheme, and are actually of domestic use. These include such things as an overmantel and letter rack, a fire screen, a book-shelf, a newspaper rack, a smoker's cabinet, a pipe-rack, and are well and

strongly made in fumed oak, with space left for the insertion of the purchaser's photograph, which, in the examples shown to us by the company, and to be seen by anyone interested at 115, Oxford Street, W., were in all cases bromide enlargements, either as developed or toned by the convenient hypo-alum or sulphide method. The illustrations which we give will show roughly the design of these articles, though they will unfortunately give no impression of their handsome and substantial appearance. The prices of the pieces of furniture may be obtained on application to the Kodak Co.

CHRISTMAS MOUNTS.—Messrs. Marion and Co., Ltd., of 22 and 23, Soho Square, London, W., are issuing a comprehensive series of mounts suitable for Christmas greetings, souvenirs, etc. They comprise both the paste-on and slip-in varieties, in single and two-fold cards, and range in size from midget to cabinet at prices calculated to meet the needs of all classes of photographers. The colours are

always, so far as we can recollect, with the fatal drawback so as the photographer was concerned that when all was said and done he would find himself converted from a photographer into an amateur carpenter or cabinet maker. That photography is capable

of being applied largely in the adornment of articles of furniture is most certainly the case, but we cannot recollect that any pieces of furniture have been manufactured specially for the incorporation with them of a photograph. This gap, however, has been filled by the Kodak Company, who, with great originality and good taste, have designed pretty nearly a dozen articles which are extremely well fitted for the reception of photographs, therewith form a decorative scheme, and are actually of domestic use. These include such things as an overmantel and letter rack, a fire screen, a book-shelf, a newspaper rack, a smoker's cabinet, a pipe-rack, and are well and

feature of the series, and one which will probably be exceedingly popular. These mounts may be obtained in either large or small quantities, and a pamphlet, giving full particulars as to prices, etc., may be obtained from Messrs. Marion, at the above address.

THE BIRMINGHAM PHOTOGRAPHIC CO., LTD., are issuing a series of postcards with appropriate Christmas designs, and those who prepare their own greeting cards will probably be glad to know that such are now obtainable. The cards are sold in the usual sixpenny and one shilling packets, as well as in bulk, no extra charge being made for the design, and may be obtained from all dealers, or from the above firm at Criterion Works, Stechford, near Birmingham.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, SEPTEMBER 27.

Royal Photographic Society. Meeting of Members of Affiliated Societies at the New Gallery, 121, Regent Street.

SATURDAY, SEPTEMBER 28.

Coventry Photographic Club. Outing to Stoneleigh.  
Worthing Camera Club. Outing to Washington, Wiston Park, and Chanctonbury.

North Middlesex Photographic Society. Outing to Hornchurch. Special Competition: A Portrait of a Member of the Society.  
Hull Photographic Society. Outing to Paull.  
Uddington Amateur Camera Club. Outing to Monkland Glen, Airdrie.

WEDNESDAY, OCTOBER 2.

Everton Camera Club. "Wandering Round Liverpool." R. Eastham.

THURSDAY, OCTOBER 3.

Liverpool Amateur Photographic Association. "Lantern Slide Making." S. L. Coulthurst.

Queen's Park Amateur Photographic Association. "Pictorial Composition." W. C. S. Fergusson.

North London Photographic Society. "Theory and Practice of Time Development." W. S. Slater.

Hull Photographic Society. Annual General Meeting.

**NOTTINGHAM CAMERA CLUB.**—The annual general meeting of the members of Nottingham Camera Club was held on September 17 in Room 75 of the Mechanics' Institution, Mr. Thomas Wright presiding. The annual report showed the present membership to be 125, an advance of nine on the year, while the average attendance at the thirteen meetings which were held was very satisfactory. The four days' exhibition proved to be one of the most successful ever held by the club, and resulted in a balance in hand of £11 8s. 6d. The financial statement was also satisfactory, and both were adopted. The following officers were elected:—President, Mr. Arthur Marshall; vice-presidents, Messrs. A. Black, A. Brown, H. Crewdson, W. Edgar, J. Houston, W. H. Kirkland, G. H. Wallis, and T. Wright; committee, Messrs. J. Anderson, E. V. Brown, W. S. Ellis, A. Hallam, W. H. Kirkland, S. D. Middleton, F. H. Radford, H. Roberts, and T. Wright; honorary treasurer, Mr. A. Black; and honorary secretary, Mr. S. W. B. Vines.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting held September 19, Mr. W. R. Stretton in the chair. Mr. W. F. Slater lectured upon "The Theory and Practice of Time Development." He said that by time development he meant placing the plate or film in a standard strength developer, at a standard temperature, for a standard time, and he should endeavour to prove that this was the only correct method of conducting development. The average amateur when, in conducting ocular development, he saw the image appear strongly upon the surface of the plate, immediately plunged the same into the hypo and obtained the ghost of an image. Had he carried development further the negative would, in the majority of cases, have been a good one. The chief trouble of all photographers had always been when to stop development. The only control lay in the time the plate was kept in the solution, and a correct exposure should be given to obtain results. At the same time a considerable range existed between correct and uncorrected exposure, the difference in, for instance, Kodak films being as large as from  $\frac{1}{2}$  sec. to 4 sec. Further, the same result as to strength and density could be obtained by any developer if the plate was kept in the solution for a time according to the developer in use. The degree of contrast

was a personal factor. To get a softer result, reduce the factor; to strengthen the contrast, increase the factor. The longer the plate was in the developer the greater the contrast, and there was a controlling method in the result. A temperature of 65 degrees was best, and the lecturer asserted that better negatives could be obtained by the method of time than had ever been made in the dark-room.

Mr. Beckett thought that Mr. Slater had put forward some strange ideas. First he said there was not control in development, and at once explained how to control development.

Mr. Teape said Mr. Slater had stated a case in which he would undertake to obtain a good negative with ocular development—ease.

Mr. Rapson could not agree with the idea that a given time stated by the lecturer, was always the best. He personally developed Kodak films in solution from the same bottle, on which was done in four minutes, whilst the other took ten hours to get a printable result.

Mr. Dawson asked if Mr. Slater would use the same method on plates, and what he would do to reduce the time from twenty minutes to, say, five.

Mr. Slater said: Strengthen the developer five times.

Mr. Stretton asked if this meant that a developer five times normal strength would do the work in one-fifth of the normal time. If so, he queried it. If Mr. Slater's contentions were correct in method of time development then all the old photographers obtained their results by pure accident, as they had worked without any principle. Given, he said, sufficient exposure, the rest could be done afterwards.

Mr. Slater said that the relative values would be altered in a case.

Mr. Teape had given from  $\frac{1}{2}$  sec. to 40 sec. exposure, and ocular development had obtained negatives, all of which gave platinum prints.

Mr. Stretton was opposed to all mechanical development, and contended that if the works of the most successful workers were examined none of the results were obtained by time development, by ocular treatment. Again, before teaching what time development was and laying down laws as to development, it was needed to tell what correct exposure was, and give laws as to how to obtain it, assuming that correct exposure could be obtained, did one want ocular development? He thought not. Each plate wanted special treatment for the result required, the negative being only a means to an end.

## Commercial & Legal Intelligence

**CANVASSING FRAUDS.**—An application was made to the City Magistrate on Tuesday by Wm. Groves, a collier, of 71, Road, Aber. Applicant asked the Bench to do something to restrain a man purporting to be a traveller called upon him and said he was prepared to enlarge a photograph for nothing, simply to advertise their business. They had decided to do that for a few in the street. Groves explained that he duly received the enlargement, was asked to have it framed for 10s. 6d. Now (said Groves) the enlargement was fading, and as he did not receive the original photograph back he wanted to know what he was to do.

Mr. R. Y. Evans (Clerk): You must go to the county-court.

Applicant: Well, I read in the "Evening Express" that Mr. F. Ham had dealt with such a case.

Mr. Thomas (Deputy-clerk): Ah, yes, but London magistrates have more power than we have here.

**PRIESTLEY AND SONS, LTD. (PHOTOGRAPHERS, EGREMONT).**—agreement under seal, dated August 20, 1907, renewing for a period of seven years a debenture, dated February 4, 1903, securing £10,000 charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holders: Mrs. C. L. North, Dryclough House, Crosland Moor, Huddersfield.

**CANVASSING AMENITIES.**—The rivalry of two photographic canvassers in Bath Street, Portobello, N.B., had given rise to a complaint amongst the neighbours, and it also led to the appearance of one of the men at the Portobello Police-court, charged with assault. The accused was Mark Chisholm, and he is at present

employed with Mr. Low, photographer. His offence was that on September 9, in Bath Street, and near to the photographic studio occupied by Mr. Wm. Lees, he behaved in a disorderly manner, and assaulted Alex. Milne, canvasser, 65, Cumberland Street, Edinburgh, by striking him with his clenched fist on the right jaw, knocking him to the ground. Chisholm, an elderly man, pleaded not guilty, and was defended by Mr. George Croll, solicitor.

Mrs. Scott, of Falkirk, gave evidence to the effect that she was talking to the canvasser when Chisholm, who was cursing and swearing, came forward and struck Milne. While Milne was on the ground accused was going to strike him again, but she interposed, saying, "Would you dare strike a man on the ground?" Similar evidence was given by Sarah Gallagher, High Street, Edinburgh, and by Agnes Fergusson, Bath Street, who had just got home from school when the offence was committed. Wm. Lees, the photographer, did not see the assault, but had his attention called to it by hearing his man falling. On going to the door and asking if it was wrong, Mrs. Scott told him of the assault.

Mark Chisholm, accused, stated, in giving evidence for himself, Milne had been calling "tin whippers" at him, and that when he went over to him complainer raised his hand to strike him, and gave him a shove. In cross-examination, he admitted having had a glass of beer. Another witness for the defence, who said she saw the fall, rather detracted from the strength of her statement by saying that she saw nobody in the street at the time near to Milne. Superintendent Currie said she must be speaking to an occasion of which he knew nothing. Wm. Muter deposed that the calling of names in the street was a daily occurrence, and when he asked Milne if he did it he replied that it was for the purpose of raising the man's rye.

After the Prosecutor and Mr. Croll had spoken, the Magistrate said he had no difficulty in finding the charge proven. It was unnecessary that the old man had taken a glass of beer, as he had admitted, as he seemed to be excitable. There was no justification, however, for him taking the law into his own hands. Taking nothing into consideration—£1, or fourteen days.

**PHOTOGRAPHER'S SUN BLINDS.**—In the Yarmouth County Court last week, Alfred William Yallop, photographer, Regent Road, sued Bert Feek, wagonette driver, Admiralty Road, to recover £12s. 3d. for a smashed window. Mr. P. Wiltshire was for the plaintiff. Police-constable Turner saw what happened, and he said the canopy irons of the wagonette caught the irons of plaintiff's sun blind, and the window frame was pulled away from the wall, the result that a window 6ft. square was smashed. The sun blind irons were about plumb with the edge of the kerb, and as the wagonette was likely to come in contact with them plaintiff had caused to have them altered. His Honour said plaintiff ought to have nothing projecting over the footway. The constable's report put him out of court. If any mischief was done by these blinds the owner was responsible. Judgment for defendant.

## News and Notes.

**THE LUMIERE N.A. COMPANY** inform us that they have now a supply of "Autochrome" plates in English sizes at the following prices:—4s. 6d., and ½-plate 10s. per box of four.

**NOTICE OF REMOVAL.**—The Warwick Trading Co., Ltd. (4 and 5, Warwick Court, Holborn), announce that owing to increased business they are removing to larger and more commodious premises at 113, and 117, Charing Cross Road, W.C., where all communications should now be addressed.

**P.S.**—The following lectures will be delivered at the New Gallery—Saturday, September 28, "Westminster Abbey," by the Rev. Wm. Perkins, M.A., F.R.Hist.S.; Monday, September 30, "The Celebrated Nesting Haunts of British Sea Birds," by Wm. Perkins; Thursday, October 3, "A Year and a Half among Savages," by H. Dunning, F.R.G.S., F.R.P.S.

**"ELOX" COMPETITION.**—Messrs. J. J. Griffin and Sons, Ltd., announce the following as prize-winners in their last monthly competition:—First prize (£2 2s.), F. Schofield, Motherwell; second (£1 1s.), Hugh W. Wilson, Glasgow; consolation prizes (5s.),

Mrs. A. Bletcher, Manchester; H. H. Tomkins, Leyton; William Frame, Hamilton, N.B.; Charles H. Woodford, Gosport; Alfred Dodgeon, Nelson; Captain H. Hurrick, Richmond, Yorks; H. Faircloth, Harlesden; Mrs. Gertrude Brooks, Port Talbot; Miss L. M. Gibson, Petersfield; D. L. Richards, Troedyrthur; Miss Edith Langsford, S. Norwood; Lionel Room, Highgate. As this competition is strictly for those who have never won a prize before, the above-named are debarred from again competing, and the opportunity for the success of other beginners thereby increased.

**FIRE AT CAMBORNE.**—A fire broke out at Trelowarren Street, Camborne, one day last week, on the premises of Mr. J. Lukey, photographer. Mr. Lukey, who was in his workshop late, was engaged in burnishing some photographs, when the lamp he was using exploded.

**LONGING LOOKS PROVIDED.**—Inserting intelligence in vacuous countenances is surely quite a new profession (writes a daily newspaper). The following is an actual advertisement which has been published by a photographer:—"Marvellous results in photos. Hair put on bald heads; charming dimples inserted in cheeks; teeth removed if necessary; thin people made stout; scowls removed from sombre faces and winning smiles substituted; homeliness banished; intelligence inserted in vacuous countenances; goo-goo eyes, longing looks, and the baby-stare furnished if desired. Classic profiles, Grecian noses, and flashing eyes a speciality."

**THE CINEMATOGRAFF FIRE.**—At the inquest at Newmarket last week the jury returned a verdict that death was due to shock caused by burns, and added a rider that in their opinion sufficient precautions were not taken by the company for the safety of the public, and that the Urban Council, who let the Town Hall, should in future exact the same provisions as the London County Council require in letting their halls for these entertainments.

**NORTHAMPTON (POLYTECHNIC) INSTITUTE.**—The provision last session of increased accommodation in the rooms of the British Horological Institute in Northampton Square has made it possible to introduce further developments in the work of the departments which continue to find their quarters in the original building as well as in that of the department of technical optics. The most noteworthy of these developments is a course on the "Production and Measurement of Light," which is being given to both day and evening students by the Electrical Engineering and Applied Physics Department, and by the Department of Technical Chemistry jointly. The lectures and laboratory work in the Electrical Engineering Department deal with all the various kinds of electric lamps, glow, arc, and luminescent; with the problems of the production of light, and photometry, and general questions of radiation. In the Technical Optics Department four new classes especially suitable for artisan students are being started, and minor changes have been made in the syllabuses. There are also special classes for the instruction of cinematograph operators, which it is hoped will meet a much-felt want and place this kind of work upon a sound scientific basis.

**LEEDS INSTITUTE.**—A photographic class will be held during the coming session in connection with the Chemistry Department of the Leeds Institute Technical School, under the superintendence of Mr. S. E. Bottomley, F.R.P.S. Full particulars may be obtained from the Institute or from the Higher Education Department, Calverley Street, Leeds.

**PHOTOGRAPHIC CLASSES.**—The photographic classes at the Cripplegate Institute, conducted by Mr. John H. Gear, F.R.P.S., will open for the winter session on Wednesday, October 2, the special class meeting at 6.30 and the general class at 8 p.m. The general class will embrace those subjects required for the examinations in photography by the City and Guilds of London Institute and the London Chamber of Commerce, and students desirous of obtaining the technological certificates granted by these examining bodies will be specially coached for that purpose. The scheme of the special class includes bromide enlarging, enlarged negatives, oil printing, the reproduction of negatives, etc. Syllabus and full particulars may be obtained from the Secretary, Cripplegate Institute, Golden Lane, London, E.C. Mr. Gear also conducts a similar class at Thornton Heath Polytechnic on Thursday evenings at 7 o'clock.

**THE LETO PHOTO MATERIALS Co.** have been awarded the highest award in the photographic section of the International Sports Exhibition at the Grand Palais des Champs Elysées, Paris (July to October, 1907), for their exhibits on the various grades of Seltona paper.

MR. BROADHEAD, photographer, of Lynchford Road, Farnborough, has received an invitation from his Grace the Duke of Rutland to attend at Belvoir on the 26th inst., for the purpose of taking photographs.

**PHOTOGRAPHERS AND THE PUBLIC.**—Apropos of the incident at a Sloane Square church, mentioned in our issue of last week, we would commend to photographers the very sensible comments of the "Yorkshire Post" on the growing disposition on the part of the press photographer to consider nothing outside the sphere of his operations:—The snapshotting photographer is going too far. During the wedding of Lady Edith King-Tenison at Holy Trinity Church, Sloane Street, the day before yesterday, a photographer who had been warned off the premises by the vicar is stated to have stealthily climbed the pulpit steps and at the right moment—if the word "right" can be used in such a proceeding—to have snapped the happy pair at the instant the marriage vows were being taken. "Is photography an art?" can only be answered in the affirmative with the reservation that in the hands of some of its practitioners it has become a nuisance, and an abominable nuisance at that. Unfortunately the wrongs committed by the "snap-shot fiends" are usually of the kind for which there is no legal remedy, none having the power to bring the culprit to book. In the case described, as it happens, the probability is that the photographer could be sued for trespass on the "vicar's freehold"; permission having been sought and expressly denied, the case is even stronger than in those instances in which it is not asked at all. But though the gentleman who operated in Holy Trinity Church may not have heard the last of his action, it is not for the persons photographed to take proceedings, since the victims of the "snap-shot" have no copyright in their faces—as they have in some of the States of North America—and can only complain with effect when the photograph is employed to render them ludicrous in the eyes of the public. If, for example, a snapshot of a Lord Mayor in a ridiculous posture—presuming the supposition to be within the bounds of possibility—were circulated as a picture postcard with the intention of holding him up to public ridicule, that would be libellous, and the victim would have his remedy in the law courts. But it would have to be a strong case, and the intention to hold the victim up to ridicule would have to be proved. The ordinary mortal as a rule will have no remedy. The position of affairs is now much worse owing to the growing use and popularity of the telephotographic lens, which will take large and easily recognisable photographs of a man or woman at several hundred yards. The unscrupulous photographer is, therefore, now able to secure snap-shots of bathers, for instance, quite unawares, to the great delight of himself and all his kidney, but to the strong disapproval of right-thinking people. It is curious that the popularity of this type of lens—which has many excellent and perfectly unobjectionable uses—should have been so long in coming, for its power was shown, not for the first time, so long ago as 1887, when a charming portrait of Queen Victoria smiling was taken by its means. In photographing the great, however, the wisdom of the "snap-shottist" usually keeps him within reasonable bounds; and the great are not likely to make any vain attempt to prohibit the telephotographer from supplying what is, after all, a creditable demand on the part of the public, and by a means which from the distance at which the pictures are taken, cannot cause them personal inconvenience. His Majesty the King has always been fairly treated in this respect, but downwards from him there is a gradual declension of scrupulousness. We have seen photographs of the Prime Minister, for instance, with one leg in the air—no doubt in the natural action of walking, but still likely to raise a smile. One may be a novelist with a conscientious horror of seeing one's face in print. Is such a one to have no protection from the telephotographer in ambush? At present for the ordinary person there is no such protection; and the only thing for the sensitive to do is to enter and never leave those courts from which Sir J. Gorell Barnes has excluded the black-and-white "artist"—or to emigrate to more enlightened lands. But it is to be hoped that an assault on a "snap-shot fiend" by his victim or a relative would not be too severely regarded if taken into Court.

**PHOTOGRAPHIC CLASSES.**—Mr. A. G. Field will conduct photographic classes for elementary and advanced students on Monday evenings at the Acton and Chiswick Polytechnic. The fee for either course for the session is 5s., and full particulars as to syllabus, etc.,

may be obtained on application to the secretary, Mr. V. C. Egge, at the Polytechnic, Bedford Park, W.

THE BUSINESS at 5, St. Peter's Road, Great Yarmouth, lately carried on by Messrs. E. Atherton and Co., has just been purchased by Mrs. M. A. Read, who will trade as "Athertons."

**A PHOTOGRAPHIC SOCIETY FOR STOURBRIDGE.**—A meeting was at the Institute last week, under the chairmanship of Mr. I. Cook, in connection with an attempt which is being made to form a photographic organisation for Stourbridge, which shall be affiliated to the Midland Federation. In connection with the Working Men's Institute a photographic club already exists, of which Mr. Cook is president, and in return for a nominal fee its members have the use of an excellent dark-room and apparatus as can be found anywhere in the Midlands. The hope and intention of an adjourned meeting to be held at the Institute on Monday week, is to attract at least 40 persons interested in photography with a view to joining the Federation, and arranging lectures in connection with that, it being rather beyond the power of the present club to incur the necessary expense. In the meantime the secretary of the club, the Institute, Mr. Jay, is endeavouring, by means of enquiries and circulars to arouse the requisite interest in the movement.

**MYSTERIOUS DEATH AT ROCHESTER.**—Mr. John J. Eastmead, secretary to the Rochester Conservative Club, died under mysterious circumstances on Monday night last. He had recently been suffering from neuralgia, and yesterday he was found lying in a helpless condition on the Rochester Esplanade. He expired soon after removal home. The deceased, who was fifty-six years of age, was in business as a photographer in Rochester.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### SKIN AFFECTIONS FROM CHEMICALS.

To the Editors.

Gentlemen,—I have noted and followed very closely the queries and correspondence in your paper recently re skin affections. I have taken note to a great extent of the various ways the skin is affected by the constant use of certain chemicals, I myself having suffered very much pain and cracking, and even bleeding, from that of which I can say is due in the first case to neglect of cleanliness. I fully agree with P. H. Adams's statement that the cause is due to the hypo and the water, and believe that "Oak Side" is true to much the same, as I cannot conceive how the sulphocyanide could have any reasonable time to affect the skin, for as soon as a batch of prints is toned the prints are washed free from any chemical the toning, and should therefore wash the fingers clean. Then comes the hypo bath, which then will finish off any remains of sulphocyanide. I am convinced in the same way as P. H. Adams that the hypo is the skin enemy, owing to myself having used one for developing and the other for fixing, the latter cracking the skin. Then, again, I am troubled if I use metol, but in quite a different way—a small blister will almost instantly appear if my hands are anywhere near it; yet at one time I could keep my hands in the developer for hours without any after effect. But, due to carelessness, I am now punished. My letter, however, is to cure and prevent skin affection by treatment, which, if used daily, will certainly prevent it, and, if the ointment is used, effect a cure. The first time on entering the work-room I smear my fingers with lanolin ("Darting" brand I prefer), and rub that well in. That causes the pores to resist the water, but after a few wipes on the towel by degrees removed, so I give an additional rubbing in of "lanoline," after the "lanoline" has been taken in. This resists very well, but the user will have to put up with the odour that comes from it. The slight stickiness will soon leave the fingers, and in case of serious bleeding or cuts I adopt finger-strips. Being thus prepared I can plunge my fingers into almost any chemical that would have nearly sent me crazy with an itching skin.

tion. My day's duties done, I then bathe my hands in the hottest water that I can bear, and wash with soap and wipe on a towel kept for final wiping. This treatment also reduces the pyro stain. It is not commonly known that soap used immediately after pyro tends to make the stain fast. I give here the ointment, which costs very little to make up. It is as follows:—

Ichthylol .....	10 grs.
Lanoline .....	40 grs.
Boric acid .....	30 grs.
Vaseline .....	30 grs.

Smear it on the fingers before retiring, and after a few applications the affected skin will rapidly heal up. By adopting this simple treatment the fingers can be kept in perfect condition. I hope that this letter will be of some benefit to any of my fellow-workers.—I am, yours faithfully,  
JAROB.  
Norwich.

To the Editors.

Gentlemen,—I have noticed the correspondence which has appeared in your journal recently on metal poisoning. As I have had a good many instances of this under my observation, perhaps it will interest your readers to learn how they were dealt with. The number of people liable to this annoying affection does not seem great in proportion to the users of this popular developer. I have found them to be mostly possessors of very dry hands. Directly the first symptoms appear—i.e., redness, slight swellings, and intense irritation—it is advisable to cover the parts affected with Lassar's paste (which any dispensing chemist will make up) and bandage. Night and morning it is advisable to bathe the affected parts in warm water, into which a small quantity of boric acid has been dissolved, say a teaspoonful to a quart.

The above treatment has always been successful in my experience, but the malady leaves the skin very tender; and for some time after it has disappeared it is as well to rub the hands with zinc ointment before going to bed and wear cotton gloves whilst asleep. My experience is that the few liable to this malady readily re-contract it, and it is wiser for them to use another developer which suits their hands, even if they do not get the same results.—I am, Gentlemen, yours truly,  
J. FINDLAY.  
London, W.C.

September 23, 1907.

To the Editors.

Gentlemen,—Re the letter of P. H. Adams concerning the above. My experience is to the contrary. My developing-hand is the one which goes wrong, whilst the one used for hypo has never had anything the matter with it. I find the only remedy is to use finger-stalls on the hand which goes into the developer. It is practically impossible to develop quantities of postcards without wetting the fingers halfway up.—Yours faithfully,  
A. W. HOLLIDAY.  
Station Road, Alton.

## THE PRESENT STATUS OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—A musical comedy company recently visited this city, and it was part of the comedian's gag and business on the stage to be ever presenting his photographic portrait to the other characters. One of the recipients tore the portrait up and threw it on the stage in contempt, which was resented by the giver, with this expression, "Do you know, Sir, that these photographs cost me 7d. a gross?" Thus, "does the stage hold the mirror up to Nature and reflect the image and body of the times, its form, and impress."

"Truth severe in fairy fiction-dressed."  
"Tis true, 'tis pity, and pity 'tis, 'tis true."—Yours faithfully,  
The Studios, 7 and 8, Park Street, Hull.  
W. BARRY.  
September 23, 1907.

[We are not prepared to take our views of the photographic profession, any more than our political opinions, from the comedian of the musical stage. While no one can disguise the fact that photographers are harassed by a plague of cheapness we have reason to know the work which is unmistakably good tends to command a better price.—Eds. "B.J."]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- E. O. PARKIN, 58, Wilkinson Street, Sheffield. Four Photographs of the Sheffield United Football Players.
- G. T. FILLINGHAM, 9, Crossgate, Durham. Three Photographs of the Rev. R. P. Love.
- J. BORROW, 79A, Waterloo Road, Middlesbrough. Photograph of Woodlands Road, Middlesbrough.
- S. KIRK, 10, Angel Row, Market Place, Nottingham. Photograph. Group of Nottingham Cricketers and Indian Mutiny Veterans with the Mayor of Nottingham and Colonel A. C. Cantrell Hubert.
- R. H. PEEL, 238, Harrison Road, Belgrave, Leicester. Photograph of the Leicester Nomads Football Club.

R. J. OWEN.—We hope to deal with the subject shortly.

GELATINE MOUNTANT.—We have been for some time past using a solution of gelatine for mounting our pictures, as we seem to get on better with it than starch. Lately we have had several returned with yellow stains upon them. The gelatine we use is an expensive foreign one, and very white and pure. We are afraid our mounter has been using it after it has become somewhat sour. Do you think this may account for the fading?—A. AND T.

We think it more than probable that the decomposed gelatine has conducted to the fading. Many of the foreign gelatines, such as that mentioned, are strongly acid and quite unsuitable for mounting silver prints. If gelatine is used it should be tested for acidity, and if found acid rejected. A few drops of carbolic acid added to the solution, when it is made, will arrest the decomposition.

J. C. COUACHE.—Try Gale and Polden, printers and stationers, Aldershot.

A BUSINESS QUERY.—I am in business here as a photographer, and would open a branch in my native town in the purely midget line, but am wondering whether the fact that I was bound in my indentures not to set up within ten miles of that town is prohibitive. I have been told that this is no longer upheld by law. Furthermore, my master sadly neglected his part of the transaction—viz., to teach me the business thoroughly. No premium was paid. Said master is still in business there. How do I stand?—C. C.

Without seeing the indenture and knowing the precise terms of it, we cannot say definitely how you stand, as so much may depend upon circumstances. If the agreement purports to restrict you from starting business, for all time, within ten miles of the place, we should say, in a court of law, this would be ruled an undue restriction of trade, and it would then be null and void. If it only restricts you for a certain period the case might be different. We should advise you to consult a solicitor, showing him the indenture.

DOUBTFUL DEBT.—Please advise me in the following:—A young lady was photographed by me some time ago, who has since died, without paying for same. I rendered account to her father, who has refused to pay, as the photographs were ordered without his knowledge or consent. The photographs were specially good, and I know that some of them are hung about the house. Failing payment, can I order return of the photographs or is the father entitled to pay?—R. D.

We should have thought that everyone was aware that if they gave credit to a minor without the authority of a parent or guardian, except for articles of actual necessity—which, of course,

photographs are not—they cannot recover the debt. However, if the young lady was of full age at the time the debt was incurred you can sue the executors or administrators of her estate, if she had one, in the county court. Of course, you cannot get the photographs back.

**LANTERN.**—May I have your advice re buying a lantern. I use acetylene jet, and find all lantern bodies too short for same, so I cannot shut down back door. (1) Are some makes larger than others in lamp-house? (2) What kind of condenser is best, and size? (3) All objectives I have tried fail to give pictures sharp at edges. Can you name a lens that will give picture sharp all over at same time and yet be large diameter, so as to make the most of the light? Of course, I mean at a reasonable price. I know there are plenty of expensive flat field lenses. (4) About what will such a lantern cost?—C. MARSHALL.

You do not say whether you mean an optical or an enlarging lantern, but from your questions we assume the former. (1) As a rule, the tap end of jet projects through a slit cut in the door. If you buy lantern and jet together the door will be adjusted so that it will close. The ordinary jet will not go right inside any lantern body. (2) The ordinary compound condenser, made of two plano convex lenses, is very serviceable, but the Herschell condenser, with a meniscus and double convex lens, is perhaps the best. This costs a little more. Use 4 $\frac{1}{2}$ in. condenser for lantern slides; 5 $\frac{1}{2}$ in. for enlarging from  $\frac{1}{4}$ -plates. (3) Cheap objectives are deficient in this respect, but no objective will do what you require unless light is properly adjusted. Write to some well-known firm that specialises in lanterns, and they will advise you re objective and price. (4) You can get a very good apparatus for about £5, and a very serviceable one for less.

**W. M.**—The book to which you refer was reviewed in our issue of August 16, 1907, page 622.

**ENCLOSED ARCS, ETC.**—(1) In your issue of March 22 is a letter on the subject of arc-light portraiture, under which you note that further mention is to be made of the subject, but I cannot find any in subsequent numbers. The point is in regard to the visual and chemical focus not coinciding. As I intend opening a studio shortly, in which I wish to instal artificial light, I should be glad to know if this defect is inherent in arc lamps (enclosed), or only in the type mentioned by your correspondent. I have used an open Boardman and do not remember any difficulty, but this is too expensive for me. I cannot alter the focussing screen, as I use the same for daylight. Perhaps you could suggest some other way out of the difficulty. (2) I have been successful with flashlight, and in my method the only disadvantages are that the lamp has to be re-charged for each exposure, and the very slight shock of the flash. Do you think such a flash system would be at a disadvantage from a commercial point of view? I mean would there be any prejudice against it in the public mind? The difficulty of the focussing and the great expense of running are against the arc, while gas is not good enough for me; its limitations are a handicap to good workmanship. I have never seen a studio worked by flashlight, except a "stickyback," and I have heard people remark that it gives such a staring appearance to the eyes. Of course, it does in inexperienced hands, but I am convinced it is a fine thing if properly worked, especially for children, but people seem to expect electric light somehow. It somewhat surprised me that no maker of arc-lights replied to the letter mentioned, either to refute the implied defect or to explain how to overcome it.—ARC-LIGHT.

(1) The effect depends upon the correction of the lens as much as upon the lens. Although there are hundreds of enclosed arcs in use we have not heard of another similar instance, although we have heard of several in the case of enlarging lanterns fitted with arc lamps. We think it most likely that you will not find any trouble with it; but if you do it can be avoided by using a filter of plain glass, which will cut out most of the ultra-violet. (2) We should certainly prefer an arc-light to flashlight, on account of the necessity with the latter of removing the smoke, either by hand in a portable chamber or by erecting a flue.

**MOXA.**—The developer was the Ilford pyro-soda, and the general reference in the article is to portrait negatives on Ilford "Zenith" plates.

**HALF-TONE.**—Could you kindly inform me (1) the process by which photographs are transferred to ordinary newspapers? (2) What are the apparatus and materials required? (3) Failing No. 1, what can I purchase a book giving very full details on the subject suitable to instruct one who knows only the ordinary photographic processes?—T. E.

We presume you mean the half-tone process, a sufficient description of which would occupy far too much space in our columns. The best advice we can give you is to get a book on the subject, such as "The Half-tone Process," by Julius Verfassner. (Liffe, 6s.)

**EMIGRANT.**—"The Photographer," 21 and 26, East Twenty-first Street, New York, U.S.A.

**LENS QUERY.**—I should be glad of your help. Having got the chance of purchasing a whole-plate lens, namely, triple achromatic lens No. 9,052, J. H. Dallmeyer, London, please let me know what work it will best do for, if portrait or landscape, and could be used on a half-plate camera instead of whole plate? I have not got the chance to use until I have purchased.—TROUBLESOME.

The triple lens is suited for much the same class of work as the rapid rectilinear, of which it was the predecessor. But it is much slower, requiring nearly double the exposure. They are frequently to be met with very cheap, as they are now looked upon as being quite out of date. Still, they are very good lenses, except that they are slow as compared with the R.R. (Of course the lens can be used on a half-plate camera if the extension of the latter is long enough to take it.)

**LENS QUERY.**—Could you kindly answer the following query in your valuable paper? My studio is 24 ft. long by 12 ft. wide, and my studio camera has Ross cabinet lens, suitable for single figures or small groups (three or four). Would it, however, be possible for me to get a lens so that I could take large groups on half plate without giving too long an exposure? I will be much indebted to you for same. I am a regular reader, and have had much valuable information from the "B.J." Thanking you in anticipation.—F. R. MURRAY.

You do not mention the focus of the lens you have. As you cannot get far enough back with it to get what you desire, you must get one of shorter focus. Probably one of an inch and a-half or two inches shorter would fulfil your requirements. With the shorter focus one you would have to stop down somewhat to get covering power, which will necessarily make it slower. One of the modern anastigmats, working at about  $f/6$ , would possibly answer your purpose. Such a lens covers a large plate in proportion to its focal length, and has a very flat field.

**FINISHING BROMIDES.**—I shall be glad if you can inform me in next issue of the "Journal" what materials are required for working up bromides, and how used. Is there a book on the subject?—BALDWIN.

There are several different methods of working up bromide such as with water colours, pastels, the air-brush, etc., or combination of them. We should advise you to get Johnson work "Retouching the Negative and Finishing and Colouring Photographs," Marion and Co., 2s. It is the only one on the subject.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

## SUMMARY.

The exhibition of The Society of Colour Photographers has been viewed with the greatest interest by the London papers. The exhibition remains open until October 26. On Friday, October 11, it may be visited up to 9 p.m. At 7 o'clock a short explanation of the processes will be given by Mr. A. J. Newton, Principal of the Old Court School of Photo-Engraving.

An exhibition of examples of portraiture by artificial light will be opened at the house of the "B.J." immediately after the close of the present colour exhibition.

The Lumière Process. We draw attention to a number of points in the manipulation of the "Autochrome" plates which require to be noted. (P. 746.)

"The Amateur Photographer's" remedy for the frilling of Autochrome" plates is quoted on page 757.

The Warner-Powrie Process. Mr. William Gamble, who was in touch with Mr. Powrie in America, reviews the history of the screen plates (P. 748.)

Herr E. Valenta has recorded his results in preparing sensitising solutions which allow of the bathed plates being quickly dried. (P. 751.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

Mr. E. J. Wall, in reviewing the exhibition of The Society of Colour Photographers, comments on the marked improvement in technique. (P. 75.)

Dr. C. E. K. Mees and Mr. J. H. Pledge have prepared photographs showing the introduction of black when one screen plate positive is printed from another. (P. 75.)

Dr. J. H. Smith, of Zurich, places the Warner-Powrie screen-plate first in its facility for giving colour prints on "Uto" paper. A mirror accessory for use in copying from screen-plate colour positives is shortly to be placed on the market. (P. 77.)

A convenient form of whirler for the drying of "Autochrome" plates liable to frill is described on page 76

Professor Cajal's paper on the Lippmann process is concluded in this issue. (P. 77.)

## EX CATHEDRA.

### Artificial Light Portraiture.

We have to announce that immediately after the close, on October 26, of the present Exhibition of the Society of Colour Photographers at our offices, we shall arrange for inspection by the public, and particularly by professional photographers, a collection of portrait photographs, the interest of which will centre in the fact that in every instance they are from negatives made in the studio or elsewhere, by one or other of the systems of artificial lighting now in practical use. The photographs will be the work of professional photographers, and will differ widely in their subjects and general character. But their common quality of origin from a negative made by other light than that of the sun, and for commercial purposes, will, we believe, give to the collection an interest which will lead photographers in business as portraitists to make themselves acquainted with what is being turned out by the current methods of artificial lighting. Further particulars of this "Artificial Light Exhibition" will be announced in due course. Meanwhile, it may be well for us to point out that no extension of time of the Exhibition of the Society of Colour Photographers is possible.

\* \* \*

### On Methods of Development.

There seems to be a tendency to revive the old controversy with regard to the merits of development by time and development by inspection, and, as usual, both sides are spoiling their cases by going to extremes. In these days it is quite useless to say that no good results are obtained by simple time development, or that nothing can be done by modifying the development. It has long ago been determined that certain modifications of the developer affect the result, and that certain variations in procedure may produce marked differences. At the same time, it has been definitely proved that development by time, with a developer of a fixed composition, is by far the most useful practical method to adopt. Nowadays we aim at producing as nearly as possible a "correct" exposure, and if we attain this a simple normal development is all that we require. It is perfectly true that we can over-expose twenty or thirty times, and by dodging and manipulating the development, still produce a fairly useful result, but few wish to do it. There is nothing to be gained by it, and though the procedure may form an interesting demonstration before a photographic society, it is not one that we care to adopt as a rule in our own dark-rooms. We know that it is easier to control exposure than to control development, hence many have adopted the method of uniform development by time, even though they are perfectly well aware that control by development is a possibility. As a matter of fact, there is very little to be done in the way of controlling development excepting when exposure is very

prolonged. With anything approaching "correct" exposure the effects attainable by modifying development are practically limited to variations of contrast such as can be more readily produced by after-intensification or reduction. At the same time it is none the less useful to be able to save a badly over-exposed plate when the occasion occurs, and a very great deal can be done in this way if the existence of over-exposure is known beforehand.

#### A Photographic Curiosity.

We have received from a correspondent a very curious photograph of what he states to be a mirage. The photograph is one of a stack fire. The stack is smouldering, and in the vapour above the stack there is a distinct representation of the top of a hedge, with a man's head appearing over it. The definition is sharp and the head is erect and greatly magnified, the scale being three times that of the head of a man standing midway between the stack and the camera. If this is a true mirage then there must be a corresponding hedge behind the stack, but at the same time the effect may be one corresponding to a Brocken spectre, that is to say, it may be simply a shadow cast upon the smoke. Presumably our correspondent has settled these points and satisfied himself that it is really a mirage. If he can give us any further information with regard to the conditions that prevailed we shall be obliged, as the effect is very interesting and curious. The position of the hedge represented and that of the sun are important points to be recorded. We assume there is no possibility of its being an effect due to accidental double exposure.

#### The Schott "Gasworks" at Jena.

One of those amusing errors, from which even the most careful editors cannot claim to invariably escape, occurs in a recent issue of an evening paper, where is solemnly printed a report of the arrest of a Japanese engineer on the charge of obtaining by trickery the plans of machinery in the Schott "Gasworks" in Jena. If this paragraph should chance to be read by the staff of the glass works established by the late Carl Zeiss and his friend Schott it may cause them some surprise to know that the Japanese engineer is supposed to be an engineer connected with the "gasworks" at Tokio.

#### Dust on Oil Prints.

A writer in the Journal of the French Photographic Society, M. L. Billioque, makes a short communication on a practical matter connected with the oil process, namely, the removal of dust and particles of hair from the finished oil print. As workers with the oil process know, such frag-

ments of extraneous matter adhere with some tenacity to the pigmented surface, but M. Billioque finds that a simple and easy method of removing them lies in the use of an indiarubber sold in France as the *mic de pain* (bread crumbs), which is used shaved to a fine point, and of the particle of foreign matter being removed without disturbing the pigment deposit. The same rubber rather more vigorously will take off the ink but will injure the gelatine film, and is thus used for putting white accents into the print.

#### SOME POINTS IN THE MANIPULATION OF LUMIERE'S AUTOCHROME PLATES.

CONTINUED experience with the Autochrome plate draws attention to various details that are not dealt with in the instructions, and yet are of considerable importance to the practical worker. So far the frilling trouble has been the most popular topic, but there are several other matters of equal or greater importance, and several causes of failure that are likely to trap the unwary.

The instructions issued with the plates being very detailed, one of the first questions that the practical worker is likely to ask is whether it is necessary to adhere closely to them in every particular. As far as our experience goes, it appears that the correctness of the final result depends almost entirely on correct exposure and correct primary development. The matter of exposure will be dealt with presently. As regards the correct development it is necessary to adhere absolutely to the instructions with the exception that the alcohol may be reduced in quantity in solution A. The next operation—that of reversal with solution C—is a simple one that needs only to be carried out to completion. If carried on too long the image is apparently not affected, but frilling is very probable. If not carried far enough, the parts that should appear nearly transparent are obscured by a muddy brown stain. The disappearance of the last trace of this stain shows that the action is complete, so the time can be governed by inspection. As regards the formula, that can be varied, provided solution E is not made up from solution C. As, however, this is a very convenient way of making up E, it is advisable to stick to the published formula for C.

The next operation—that of redevelopment—is also one that is carried to a simple finish, and the developer, therefore, can be modified considerably. The formula given is rather weak, and we prefer to strengthen it so as to shorten the process. We find, in fact, that any strong amide

#### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

The forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### SCREEN-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\* \* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

loper, containing about five grains amidol to the acid and no bromide, can be used, and we have employed acid amidol developer with perfect success. An fine developer would no doubt be risky, hence it is able to keep to amidol, but it does not appear that exact formula is of much importance. It is, however, great importance that the redevelopment should be complete, and while there is no difficulty in watching it, there is a very simple cause of failure that most of us seem to have overlooked. If the reversed plate is not exposed too long to daylight before redevelopment, it acquires a "solarised" condition, and then develops either very slowly or very imperfectly. If dried for the purpose of binding, or of varnishing the edge, proceeding with the rest of the operations, either redevelopment should be carried out immediately after binding, or the plate should be kept in a closed plate until ready to proceed. If left for an hour or so before daylight, the redevelopment may fail.

After redevelopment we use solution E to destroy the loper. As this is also a reducing solution, it is unable to stick to the formula and to the time—ten seconds—as given.

The intensifier specified is a good formula, and works well in our hands. Probably any good silver intensifier will work as well, but there appears to be no need to depart from the formula. The time is a matter of personal judgment alone, as is also the question of intensification. As regards the clearing and fixing operations, the action of the former is somewhat vague, as we do not quite understand how it acts, we keep to the instructions. The fixing bath, however, obviously is an important part, seeing that if all operations have been properly conducted up to the time of its application, the image and brightens up the image to a very considerable extent. We are not certain whether prolonged fixing does harm to the image, but we do not get the full benefit of the bath if we under-fix. Two minutes appears to be the right time, hence in this respect it is also well up to the instructions.

A somewhat doubtful-looking feature of the process is the very short washing of five minutes after fixing. It does seem long enough, but we have not tested the point. We have, however, sometimes used permanganate as a eliminator without any apparent ill-effects, and this seems to us to be a rather desirable precaution, especially in the case of a plate bound with rubber surgical tape. If the eliminator is used, we think it advisable to remove this as soon as the plate is dry. This is readily done if a sharp knife is drawn round the film just inside the tape, the tape is tearing the latter off. The upper film around the margin comes off with the tape, leaving the lower film, if the plate is then varnished the cut edges of the upper film are well sealed.

As regards varnishing, the best varnish appears to be a solution of gold dissolved in amyl acetate. This is perfectly suitable to use, but it is advisable to beware of commercial gold varnishes containing alcohol or other volatile substances of the film. The plate is warmed so as to ensure perfect dryness, flooded over in the usual way with a rather thick varnish, and then dried on the whirler.

Drying only takes about two minutes, so the process is a quick one.

One of the minor troubles met with is the appearance of air-bells on the film in some of the various solutions. It is advisable to note that these should not be removed with the finger-tip, for it appears to be quite impossible to touch the wet, delicate Autochrome film without leaving a very obvious finger-print. Cotton-wool should be kept handy for dealing with air-bells, and we also strongly recommend its use for lightly wiping the film when washing after solution C. We are certainly of opinion that this adds to the cleanliness of the final result, and we think also that the same consideration of cleanliness renders it advisable to use solution C once only, not several times over, as stated in the instructions. We have experimented with a used solution on an ordinary negative, and in the result found black specks in the film that could not be removed at all readily. A clean image is most desirable in an Autochrome, and anything that appears likely to be detrimental to it is a thing to be avoided.

We now come to the important matter of exposure. Our experiments up to the present have, however, only proved that on this question of exposure there is much to learn. It does not appear that we can exactly regulate exposure by the same means that we employ in ordinary photography, but one or two points have been ascertained that are of some considerable importance.

In the first place, over-exposure gives a pinkish tint over the whites, while under-exposure gives a bluish tint or fog. The blue is very marked, with bad under-exposure, and it not only affects the whites, but changes yellows to greens, and yellow-greens to blue-greens. The best test for under-exposure is, perhaps, the change in the greens, while for over-exposure the pink on the whites is a good indicator to go by. With over-exposure very light tints tend to disappear, while strong tints become lighter. Slight under-exposure seems to strengthen the tints, while bad under-exposure weakens them and renders them dull and muddy. The effects produced, however, vary enormously with the light and time of day. In bright mid-day sunlight a very little over-exposure is serious, and "full" exposures must be avoided. It is then better to err slightly on the side of under-exposure, but later in the day and in the shade under-exposure is the most important thing to avoid. Very slight under-exposure will then ruin the plate, and very ample exposure is necessary. We are assuming here that a light-meter is used for ascertaining the "correct" exposure in accordance with methods previously described. From the facts stated it is, however, obvious that the meter cannot be giving exactly correct results as regards the Autochrome plate, and that in using it we must make allowances for the time of day and brilliancy of the light. Until this matter has been more carefully studied, we must then depend to some extent on empiric modifications of the exposure.

In the exhibition now open at these offices two plates showing the pink tint due to over-exposure and the blue due to under-exposure are on view. Many have found great difficulty in recognising the effects of wrong exposure, and a glance at these results will show the effects that should be looked for.

DEATH has recently taken place of Mr. George Churchill, of Wootton, a retired photographer, for some years resident in the village, who formerly carried on business at Eastbourne, where he was well known.

CHANGE OF ADDRESS.—Mr. W. T. Whitehead, so well known for his skill in all matters connected with advertising, draughtsmanship, and whose services are much in demand by those requiring really good and artistic work of such description, has removed

from the offices he has so long occupied in St. Bride Street, to more commodious premises at 10 and 11, Fetter Lane, E.C. It may be an item of convenience to Mr. Whitehead's numerous clientèle if we mention that his telephone number is now 8,261 Central.

KIDDERMINSTER AND DISTRICT PHOTOGRAPHIC SOCIETY.—Mr. H. W. West has been elected hon. secretary of the above society, and all future communications should be addressed to him at 12, Shrubbery Street, Kidderminster.

## COLOUR PHOTOGRAPHY BY THE WARNER-POWRIE SCREEN-PLATE PROCESS.

[The article on the Warner-Powrie process which appears below, from the pen of Mr. William Gamble, editor of the "Process Year-Book," is partly retrospective in its character, but none the less interesting in that respect in its account of the line-screen-plate process, which we have brought before our readers in the issues of the "B.J." for September 13, 20, and 27. Mr. Gamble is the only Englishman, and one of the very few individuals, who have been in touch with Mr. Powrie during the earlier period of his work. As his impressions were first gathered in Mr. Powrie's laboratory in Chicago, his estimation of the commercial possibility of the process should be all the more deserving of a hearing.—Eds. "B.J."]

### THE HISTORY OF THE WARNER-POWRIE PROCESS.

It is difficult to say whether it is a fortunate or unfortunate circumstance that the Warner-Powrie process of colour-photography is brought into the full light of publicity after the successful introduction of the Lumière "Autochrome" plate. Certainly it is unfortunate, because the great bulk of photographers who have not followed very closely the chronological order of the development of colour-photography will be apt to think that process is not novel, and is simply an outcome or modification of the Lumière process, whereas it actually ante-dates, and has possibly in some degree suggested, the latter. On the other hand, I think the occasion is fortunate, because the enthusiasm developed by the "Autochrome" plate makes it easy for the photographic public to understand and appreciate such a process as the Warner-Powrie one, when it might otherwise have seemed complex.

I doubt whether the majority of photographers would have understood and grasped the full significance of the Warner-Powrie process had it not been for the propaganda in connection with the "Autochrome" plate, and, therefore, instead of being a dangerous rival, the latter really paves the way for a plate or process which, in my opinion, yields more brilliant results, and is infinitely more practical and simple, while possessing a much wider application in the field of colour-photography.

#### Early Results of the Process.

It is now nearly two and a half years ago since I first met Mr. Powrie in the studio of the Barnes-Crosby Co., in Chicago. He was then carrying out some work in colour processes for this concern, which is the biggest photo-engraving firm in the United States, and disputes with Carl Hentschel here in London the claim to be the largest photo-engraving house in the world. Mr. Powrie showed me specimens of his process of screen-plate colour-photography so modestly that I might have thought they represented the fruits of a casual experiment, and arose from merely a little incident in his everyday work. But I had no sooner examined these results than I felt they portended an entire revolution in the methods of colour-photography current up to that time.

I could not believe my eyes at first. I was inclined to suspect some "fake." The result I held in my hand was so immeasurably superior to anything I had seen before in the way of colour transparencies that it seemed incredible that it could have been produced by the purely automatic action of photography. It was the portrait of a little girl in a garden, and it had all the glow of life and realism of nature, such as one sees on the ground-glass of the camera, and has so often longed to fix on the photographic plate.

#### A Puzzling Principle.

There could be no deception about it. The plate was not even sealed with a cover-glass, and the film surface looked just like an ordinary negative. I took out my pocket magnifier and asked permission to examine the plate, which was cordially granted. Then I saw the familiar striped screen of the Joly process—the alternate lines of red, green, and violet, but ever so much finer than I had ever seen them in the Joly results.

Still I was puzzled. The use of the parti-coloured screen taking and viewing I well understood, but here was a screen the photographic plate itself. It seemed incredible. Then Mr. Powrie explained that the screen was put on the glass before the coating of emulsion was applied, and that the exposure was made through the back. Well, that seemed feasible. But surely a negative image must give negative or anti-chromatic colours, and the plate I held in my hand was a positive, and showed true colours of the natural object represented. Yet, logically, of course, if it was possible to make a negative colour result, must be possible to make by some means a positive and complementary picture from it, and Mr. Powrie enlightened me by explaining that he was able to make a positive screen-plate reproduce the negative image. Nevertheless, it still bothered me, just as it has since troubled even so good an authority as Dr. Mees to understand how a coloured line-screen positive could be printed from a coloured line-screen negative. The old adage, "seeing is believing," was again exemplified.

#### Miss Warner's Part in the Process.

I afterwards had the pleasure of meeting Miss Warner, who has been associated with Mr. Powrie throughout the experiments which are now culminating so successfully. It is no secret that Miss Warner has furnished Mr. Powrie, an old friend of the family, with the necessary financial aid to carry out his invention. But Miss Warner has done more than this: she has taken a deep and untiring interest in the experiments connected with the process, and has assisted in the laboratory work. Mr. Powrie gratefully admits that his success is due to Miss Warner's ability to comprehend the utility and importance of his invention, and to her faith in its ultimate success. Her share in the invention, he declares, is more than a co-partnership interest, and that is why he insists on calling it the Florence Chromo-Process.

#### Mr. Powrie's Experience.

Mr. Powrie was originally working in the half-tone process when it was in its crude state, and had to be accomplished by means of plaster casts from swelled gelatine, over twenty years ago. He was engaged in a half-tone business in Milwaukee in 1892, and from thence he migrated to Chicago to join in partnership in a three-colour business in 1896. He was one of the first to apply the present-day three-colour process to lithography. About this time was formed the International Colour-Plate Company, which proceeded to work the MacDonough process. The company eventually failed after spending, it is estimated, nearly \$500,000 (£10,000) in its attempts to find a way to colour photography through the MacDonough-Joly methods. It should be remembered that this company attempted to introduce the process into England, opening an office in London, and showing some results at the Royal Photographic Society's Exhibition of 1900, without, however, arousing any enthusiasm.

MacDonough began a systematic study of colour, afterwards taking up photography, and finally endeavouring to carry out the idea put forth by Ducos Du Hauron some time about 1860 of using parti-coloured screens. He first tried to stipple a screen by spattering it with colour; and another of his numerous i-

as to powder the surface of a glass-plate with particles of coloured glass (a very good anticipation of the Lumière starch-grain process). Eventually he decided to confine his efforts to ruling screens, and had constructed for him most elaborate machinery.

MacDonough never got any further than using a separate ruling and viewing screen, as in the Joly process, except that he was able to rule finer screens. He did not live to see the outcome of his efforts.

### Expensive Litigation.

The reason the MacDonough process failed was that no cheap way of producing the colour-screen could be found. But Mr. Powrie developed his plan of doing it by means of bichromate printing from a ruled screen of black lines. He applied for a patent on it in 1901, which he only secured after expensive litigation. His application was contested by Ellsworth E. Flora, who was general superintendent of the International Colour Company's works, and who claimed priority for the invention. Flora claimed that he prepared his screen in the same way as Powrie, and submitted a specimen. But a microscope revealed an intervening streak of transparent gelatine, which his patent authorities maintained to be inconsistent with the alleged method of Flora. The Court, with a Solomon-like wisdom, gave Flora the opportunity of proving the claim by making a screen like Mr. Powrie's, but the challenge was not accepted. An appeal was taken, which resulted in the ruling of the Patent Commission being sustained. Then a further appeal was made in the Court of last resort in such cases, and the final decision fully sustained Mr. Powrie's claim. The cost of the litigation was paid by Miss Warner, and she worked indefatigably with her legal adviser to bring the matter to a successful issue, believing, as she did, so strongly in the justice of Mr. Powrie's claim. Since then the International Colour Company appears to have disappeared from the field.

### Making of the Screen-Plate.

For the past three years Mr. Powrie has been busy perfecting his ideas, first in Chicago and latterly in New York. He has evolved a systematic way of making the screen-plates by printing them on bichromated gelatine from a specially-ruled Levv screen. His method was described in last week's *BRITISH JOURNAL OF PHOTOGRAPHY*, so that I need not repeat the details. I would only say that it is just such a method as will strike any photo-engraver as being thoroughly practical. By adopting a ruling as light for printing, and providing a framework which holds the screen-plate always at the same distance from the light, and also by arranging the operations to follow in a regular mechanical sequence, there should not be any doubt about securing absolutely uniform results. The only difficulties I can conceive will be those due to dust and air-bubbles during the coating of the plate, but with proper precautions these can be avoided, just as they are in any dry-plate factory. I understand the coating of bichromated gelatine is put on with a whirler, as in photo-engraving, and although this is not such a mechanical way that used for coating plates with gelatine bromide emulsion, ensures, at all events, an extremely thin coating.

### An Optical Aid.

The method of placing the sensitised plate a second time in contact with the "mother-screen" without requiring elaborate means for registering it parallel to the first impressed set of lines seems to me a very pretty one. Mr. Powrie takes advantage of the appearance and disappearance of moiré patterns when one line system is superposed on another. If one rotates over a single-line or cross-line screen in contact with another, extraordinary patterns are obtained, and they disappear the moment the lines become exactly parallel to each other. Mr. Powrie makes his apparatus so that a slight turn

of a screw one way or another causes these patterns to vanish, and then he knows the screen and plate are in adjustment.

### Printing in the Third Line.

More ingenious still is the way he prints through the transparent space found between the first two lines to make the third line exactly fill the vacant space. It is altogether an extremely well-thought-out method of making the screen, and I hardly see how it can be improved on. It might be possible to impress the screen image on to the glass plate with a rubber stamp or roller, but the lines would undoubtedly be thicker at the edges, and would make an overlap of double thickness, forming almost opaque parts, and giving consequent streakiness to the negative.

By Mr. Powrie's method there is neither any retardation of the light by black separating lines, nor dilution with white light through the coloured lines being separated from each other. All the light must pass through the coloured lines, and by making an emulsion of suitable panchromatic quality, its sensitiveness agreeing with the absorptions of the coloured lines, great rapidity can be obtained, together with the utmost brilliancy of the colours.

### Simplicity of the Process.

If the Warner-Powrie process ended with the production of the negative, and it was converted by a reduction process into a positive—as no doubt it could be by a method analogous to that adopted by Lumière for the "Autochrome" plate—it would in itself be a great accomplishment, but the ability to print as many positives as may be desired merely by contact is of immensely greater importance. Mr. Powrie might well be content to rest there, and, perhaps, from a tactical commercial point of view, it would have been better to do so, keeping the further developments "up his sleeve," so to speak. I am afraid that the description of his method of preparing duplicates and printing on paper is apt to confuse the majority of photographers who are not inclined to go deeply into things, and to make them think his process is a complicated one beyond the capacity of the average man. Demonstration will soon dispel this, as the process is really very easy and requires the simplest apparatus.

This latter feature is one that distinguishes the process from many others that have been put forward. Practically, the photographer employs his usual apparatus and materials, except the special plates. He does not require any special camera or dark-slide, and he can extemporise with an ordinary printing-frame if he desires to adopt one of Mr. Powrie's methods of duplicating the results. Moreover, there is the choice of any system of lighting for the printing—either daylight or electric light (arc or incandescent) and gaslights. For development of the plates it is simply ordinary routine and ordinary chemicals. All this will appeal to the amateur who does not want too much trouble with the processes he takes up.

### Application to "Uto" Paper.

I am afraid many people will think Mr. Powrie's claims are so numerous that he is romancing, whereas he is only stating in sober fact what he has accomplished. In rendering the use of the Uto paper practical, he has done an excellent thing, because it promises to be one of the easiest and most direct ways of making colour prints on paper. Nothing has been said yet of the application of the screen-colour plates to stereoscopy and the lantern, in both of which directions Mr. Powrie has done good work.

### Usefulness for Three-colour Block-making.

Finally, what to me is the most interesting application is the duplicating (or, rather, should I say triplicating) his screen-plate negative to form a set of continuous tone-negatives for three-colour block-printing. I would refer my readers to the explanation of this process under the heading, "Three Negatives from One," on page 689 of *THE BRITISH JOURNAL OF PHOTOGRAPHY* (September 13), if they have not fully grasped this appli-

cation of the process. It will put a great power in the hands of the process block-maker if plates made in this way can be utilised. It will enable him to send a photographer with an ordinary camera to any picture gallery, or to take any view required in colours, and to quickly obtain a colour transparency which will not only be an effective guide for the etcher and the colour proofer, but will give him from the negative trichromatic a set of positives from which he has only to make half-tones in the customary way by transmitted light.

#### The Coming of the Coloured Newspaper.

Such an application of the Warner-Powrie process will be an immense stride forward in three-colour printing, and will bring

us nearer to the possibility, always hoped for, of obtaining coloured pictures of current scenes, at least, for our week illustrated papers, if not yet for our daily newspapers. The will also be an important field for the process in preparing blocks for coloured picture postcards, and in colour-lithography it can be a useful adjunct by reason of the facility with which the colour stones or plates can now be prepared from continuous tone negatives by such methods as the Frey process, which make use of a bitumen grain.

In my opinion, the advantages claimed for the Warner-Powrie process are by no means exaggerated, and it only needs the aid of the dry-plate maker to bring the process into everyday use.

WILLIAM GAMBLE.

## IDEAL PORTRAIT PHOTOGRAPHY AND PRACTICAL ART.

Up till quite recently photographic art-literature has been produced solely for the consumption of the amateur, who has fattened upon it, if he has not gained "tone," as the doctors say. The professional man has been pretty constantly beneath the notice of the critics and teachers. And this has gone on in spite of the fact that professionals here and there in London, Edinburgh, New York, and many other cities in the United States were capable of producing photographic portraits with as much skill and taste, to say nothing of correct likeness, as any of the amateurs who shrank aloof in the superiority of their own "artiness." This fact must signify that the mass of professionals were thought to be as swine before the pearls of art-teaching, and that the few who were admittedly artistic did not require any lessons.

At last, however, a teacher has arisen for the struggling shop-keeper. He is Otto Walter Beck, and is described as "Instructor in Pictorial Composition, Pratt Institute, and member of the Architectural League, New York." We welcome his book,\* not only on account of its intrinsic merit, but because it augurs a happier state of things. There is no reason, physical or moral, why the professional man should be considered dead to art. The fact that he has too often to truckle to the wishes of his customers only points to the awful difficulties that beset his path. The amateur who uses the camera for love and not for money knows nothing of these uphill tasks. His failures he destroys, and nobody knows how many. But it does not pay the man who has to support an establishment for photograph-taking and selling to destroy his work. He has to learn the great art of making a success every time, pleasing his sitter and working up his reputation in the same operation. In his own way he does admirably well, and he has developed rapidly. Many of the regrettable practices alluded to in the book are now things of the past in any well-conducted studio. Here and there he has wisely taken a hint from the leisured and successful amateur; and, more wisely still, he has so far had artistic discrimination enough to avoid the blatant faults which the wish to pose as an artist has led the amateur to commit.

It is too much to say that Mr. Beck's book, and even a hundred others like it, will endue the professional with artistic righteousness; but its recognition of him as a thinking being will, at any rate, help to break down the general impression that the mere professional is a hopeless mechanic, who has taken to his trade, not because he had any natural aptitude for portraiture, but because other things have failed, or because he started in it as an errand-boy.

When one considers the amount of experience acquired by

the professional over that gained in the intermittent leisure of the amateur, the thought occurs that the former might, if he would but let himself go, easily match the latter in the nicety of pictorial work, which are, after all, not opposed to good technique and execution. Mr. Beck's art principles, if read, marked, and digested, would place the two classes of workers at once upon an equal footing. For, after all, the amateur usually as destitute of art training as the veriest scavenger until he, on his part, has picked up some unconsidered trifles from books, lectures, other men's work, and so forth. The truth is quite obvious to any one who watches the career of a typical club man from the time of his "Brownie" boyhood to the day of his becoming a member of the R.P.S., or even "Link." Let the professional man, then, learn these things and use them for what they are worth. Let him absorb the principles of composition, of light and shade, and all the rest of it. Whether he adopts the Beck methods of salvation, background, or some other method, matters not a jot. All roads in this field of work lead to Rome. He will probably find Mr. Beck's well-distilled axioms and clearly-expressed advice can help him swiftly enough along the path—swiftly enough, at any rate, to catch up with the amateur who graduates in art largely by the example and precept of his brother amateur at the local society. In one respect the book is saner than many that have appeared upon the subject of pictorial photography. It does not set out with the assurance that photography is a fine art, and that the great mass of painting is but awful daubing to be despised by the man of superior taste. Mr. Beck, in his opening chapter, says:—

"Art in photography would be undeservedly exalted were it to maintain that the mental and emotional expenditure in production rivals, or even approaches, the output that is attendant upon picture painting."

This is healthy, at any rate, and the author has the wisdom to go to accredited works of art for confirmation and exposition of his own theories. He has a particularly simple and graphic way of forcing home his meaning, while the diagrams he uses are obvious in their truth to the most uninitiated mind.

Of course it is easy to theorise, and upon art subjects anybody and everybody can do it. Moreover, art principles are due to their inception much to the feeling of the individual. Results of beauty in works of art can be fitted with as many different theories to account for them as there are exponents. But that does not matter. All are right from their different points of view, and all are interesting and informing. Mr. Beck's are quite as adequate as any others, and they are not far-fetched. Their great value to those minds who have not yet approached the subject will be their power of inducing further cogitation.

\* "Art Principles in Portrait Photography." By Otto Walter Beck. London: B. T. Batsford. 12s. 6d.

independently. The following paragraph, for example, is enough of itself to make one good lesson:—

"Photographers have sincerely tried to understand beauty; but, failing to discover its relation to the pictorial, their efforts have been misdirected. They have usually sought a fine type of man or woman, relying for their efforts upon the character of the one and the grace and loveliness of the other. The truth that beauty is born of treatment cannot be grasped at once, nor is it easy to understand that the plainest sitter affords material as rich for pictorial beauty as does the physically perfect face or form."

Here, again, is a suggestive sentence:—

"The minute analysis of what constitutes the difference between 'light and dark' and 'light and shade' is necessary."

The author's chief method of arriving at artistic results may be briefly stated as follows:—He does not set up the whole *mise-en-scène*, accessories, background, and all; but he prefers to take a good photograph before a plain background, and then to bring into harmony all the parts of the figure, to enhance the force of the idea and of the pose, and generally to make the effect agreeable to the utmost by working upon the glass side

of the negative with two painting mediums, of which he gives recipes. To do this, of course, certain principles of art must have been thoroughly absorbed and assimilated by the photographic artist, and these principles are expounded in the former portions of the work. Reproductions of photographs worked in this way are given as examples.

Now, the captious and critical may look at these examples and demur as to the undoubted improvement over the plain and untouched prints. But this is not the point. The value of the work lies in the clear enunciation of principles which are certainly sound enough. Their judicious application is alone that by which pictures must stand or fall.

Quite recently we have had books upon art in photography, of which the empty and rambling theorising is little more than unproductive rhodomontade. Such a charge cannot be brought against the succinct manner and matter of this.

It is to be hoped that the book will be well circulated amongst those for whom it is written, for, if studied with care, it will certainly induce habits of thought, and send its readers with new and hungry eyes to the works of the best portraitists, ancient and modern, and that, after all, is the most profitable system of education in these matters.

F. C. TILNEY.

## EXPERIMENTS WITH CYANIN SENSITISERS.

[A Paper in the current issue of the "Photographische Korrespondenz."]

In the case of the majority of the modern dyes of the cyanin group, such as are placed at the present time upon the market for photographic purposes by a number of firms, the clearness with which the sensitised plates will work is dependent upon the greater or lesser speed with which the bathed plates can be dried. It is, therefore, an advantage to hasten the drying by any satisfactory means. For this purpose the use of alcoholic solution of the dyes has been recommended in many quarters; also, drying with moderately warm air; and a combination of these two methods has proved itself satisfactory. In the Imperial School of Graphic Arts, Vienna, an apparatus has been used for the rapid drying of the bathed plates by the aid of heat, and another apparatus on this model has been used by Von Hübl in his laboratory. In the case of plates sensitised in water-solutions of the dyes, drying takes place in this apparatus in one to two hours, but under similar conditions and with a dye solution composed half of water and half of alcohol the plates dry in fifteen minutes.

My experiments were made in the first place to ascertain what proportion of alcohol the bath may contain in order to obtain the greatest possible speed of drying without injury to the plates. The experiments embraced the well-known dye sensitiser, pinachrome, pinacyanol, dicyanine, and ethyl red, the first of which has been used for three-colour work, whilst pinacyanol and dicyanine have been frequently employed for spectro-photographic processes. It will be seen that when using a larger proportion of alcohol, even after a prolonged time of bathing, the effect of the above sensitisers was subdued. Plates of quite exceptional qualities as regards clear working were obtained, but the times of exposure had to be appreciably prolonged, and the minimum at the Fraunhofer line *b* was obtained more sharply.

It is therefore evident that when using sensitising baths containing ethyl alcohol the percentage of alcohol must not exceed

40 per cent. The most favourable action resulted from this proportion of alcohol in the case of pinacyanol, very clear plates being obtained with this bath.

Baths containing alcohol being particularly liable to give markings, my further experiments were directed towards employing methyl alcohol in place of ethyl alcohol in the preparation of the baths. The best results were obtained when the solutions contained 50 per cent. of methyl alcohol, and when this was done the result was better than those with ethyl alcohol only in the case of dicyanine.

In the case of ethyl red the methyl alcohol was not found advisable, the plates working far less clearly than with the ordinary alcoholic bath. Acetone in the sensitising baths acts similarly to alcohol, accelerating the drying of the plates and possessing the advantage over ethyl alcohol that markings do not take place, even with a very high percentage of acetone. As acetone is not much dearer than pure alcohol, and as the baths can be used repeatedly by the addition of further quantities of the dye stock solution, the use of a bath of this substance would appear to have something to recommend it. The most favourable results were obtained with 50 per cent. of acetone, which was found to work well with ethyl red, pinachrome, and dicyanine, and less favourably with pinacyanol, for which dye I can recommend a mixture of equal parts of alcohol and water. For the other three dyes, acetone with an equal part of water was found to give a very satisfactory bath.

Before closing the account of these experiments mention should be made of two isocyanin dyes placed upon the market by the well-known Bayer firm, of Elberfeld, under the names of "pericol" and "isocol," which were examined in a similar manner to the above and proved themselves amenable in both cases to the use of an acetone bath, whilst "isocol" works well with an ethyl alcohol bath.

E. VALENTA.

R.P.S.—The following lectures will be delivered at the New Gallery:—Saturday, October 5, "Wedgwood: His Life and Work," by Harry Barrard; Monday, October 7, "Ancient Egypt," by C. J. Marshall, A.R.I.B.A.; Thursday, October 10, "The Romance of Insect Life," by F. Martin Duncan, F.R.P.S.

NOTICE OF REMOVAL.—M. Gabriel Fermé writes that, owing to continued increase of business, he will remove to more commodious premises at 55, Boulevard de Strasbourg, Paris (Xe.), on October 15, after which date all communications should be addressed to him as above.

## THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

In concluding the review of the pictorial section of the R.P.S. Exhibition we cannot find space to refer to every photograph or even to every exhibitor, but the prospective visitor who runs his eye over the following notes will be able to pick out what is best in the pictorial work on the walls.

### THE PICTORIAL SECTION.

#### Seashore and Shipping Scenes.

This subject leads us to speak of "Beaching a Coble at Staithes" (No. 179), the excellent and spirited subject by C. E. Wanless. The action of the men, the motion of the sea, and the tossing of the boat could hardly be better done. It is a thoroughly satisfactory enlargement, wherein the tone values appeared not to have suffered a whit. "Land's End" (No. 113) and "Sea Mists" (No. 143) are two fine coast scenes by W. T. Greatbatch. The rocky shores have an undoubted appearance of that desolate and hopeless look which such scenes convey to romantic minds. There is good composition and a sense of motion in G. L. A. Blair's "Dutch Barge" (No. 305) and a fine arrangement of material in "Liverpool Docks" (No. 18), by H. J. Elliott, who has produced a delightfully silvery print. In "Under the Pier" (No. 26) Ellis Kelsey has given a striking effect of sunlight gleaming amongst the heavy structures and in the puddles which belong to the lower storeys of piers. "Marine" (No. 6), by T. Steidel, "The Quay, Ostend" (No. 10), by Oscar Hardee, and "Waiting for a Breeze," (No. 11), by W. A. I. Hensler, are three good sea-pieces. In the first the tones are well caught, particularly those of the atmosphere and the smoke from a funnel, whilst the sun and its reflection upon the water are convincing in their force. The other two are fine too, though of more ordinary treatment, Mr. Hensler's motionless vessels helping in a nice effect of mist and light. Of the sea-pieces bearing the accredited name of F. J. Mortimer, we prefer "Running Home" (No. 70) and "A Freshing Breeze" (No. 133). The first has fine movement, and the other almost deceives the eye by its irresistible impression of the swing of its single wave. Bertram C. Wickison's "On the Tide" (No. 208) suffers only from an unnecessary heaviness in the sky. Straightforward in manner and very pleasing in its general effect "The Thames at Limehouse" (No. 161) with barges and tugs is highly creditable to its author, Walter Selfe. And before we leave the water subjects we should mention the extremely nice "Winter on the River Lea" (No. 63), by W. Rawlings, adding merely that we do not quite approve of the general lightening of the right side of the print.

#### Streets, Towns, and Buildings.

The run upon Bruges has not abated. It was going strong last year, and this year it is as noticeable. The bridge is the favourite; the belfry seems to have had its day. Albert Valcke's "Old Bridge" (No. 29) is very pretty, and we may safely say as much of his "Béguinage de Bruges, Matin d'Hiver" (98). The bridge is supported by more of the houses in D. Feledi's "Motive from Bruges" (No. 111). The "Bruges" (No. 132) of J. H. Gear is nice in selection; but perhaps a little too obviously forced in effect. W. Davenport's "Bruges" (No. 308) shows us the bridge again, exactly as we had it once or twice last year. Mr. Gear grants us a little variety in his other city view, which is of "Burgos" (No. 140), a first-rate subject with a peculiarly softened treatment. C. F. Stuart's "Auld Reekie" (50) is so much "controlled" as to give undue prominence, we think, to the merely reekie. His "Shambles, York" (No. 92), with its wet pavement, is capital, if its strong contrasts do not mar it. Near together hang Arthur Staddon's "Chioggia" (No. 64), and B. C. Wickison's "Corbridge" (No. 66), both prints showing great feeling. The former sends also "Venice" (No. 75), and a better thing called "Early Morning on the Rialto" (No. 238), excellently carried through but for a little heavy smudginess in the sky. Mr. Wickison's oil-print of "Marylebone Road" (No. 294), with the Horse Guard wringing down the street, has an effect almost too brilliant in its contrast—the danger of this process.

The works of A. H. Blake are always executed with taste and feeling; but it seems to us that his subjects are, in themselves, sometimes rather poor. Perhaps this goes to their pictorial credit. "Grey and White" (No. 93) has this peculiarity we think. "The Gondola Pool" (No. 114) which at the Salon we took to be in Venice,

appears to be at Earl's Court. There, again, is a feather in Mr. Blake's cap. We need not dwell upon his other duplicates. "Reflections" (No. 281) is certainly good; but who but Mr. Blake would think of such a selection? We should like Lette-Verein's view of the "Wartburg" (No. 104) were it not in such violent contrasts. His "Kloster Malchow" (No. 104), however, is of fine and simple effect, and occupies the place of honour on the north wall. The play of light in it is well studied, and its size and dignified appearance are of the utmost value in the appearance of the gallery. Aubrey Harris's "Ludgate Circus" (No. 109) is a little tame, as, indeed, that place sometimes is. "Dingy London" (No. 116) approaches nearer to the fine broad effects of London, though we dislike the sudden patch of light in the sky. There is something strong and irresistible about the two sunny gables in A. Elliott's "De Dammetje-Paarl, Cape Colony" (No. 120), and an arresting effect in the rainy vista of Tower Bridge, which O. Hardee calls "A London Portal" (No. 121). The selection is quite admirable, emphasising the immensity of the structure. A queer collection of picturesque gables is given in "Aus dem Bergischen Land" (No. 211), by E. Quedenfeldt, and a black one in "Der schwarze Giebel" (No. 213), by O. Erhardt, a print of fine values. But the best work of Dr. Quedenfeldt is undoubtedly his "Hühner-Hof" (No. 303), a yard where a few fowls are picking their meal in the sunshine, which is given with remarkable truth and quality. This is entirely an "artist's picture." That J. Steidel's "Tyroler Burg" (No. 270) is not exactly a taking thing is due to some unfortunate choice in the colour of the print; for the subject itself is noble and romantic enough, and the effect of sunlight glaring upon the roofs is entirely in accordance with natural effect. "Eifeldorffbrücke" (No. 276) is a capital village scene by O. Scharf, just a trifle hard. If the red colour is a little unsuitable, and the composition not over good, yet the sun-flickerings through the trees are enough to make a fine thing of S. Jaffé's large print, which the catalogue rather doubtfully gives as "Gracht im Haag" (No. 294). (What is this "Gracht," which is in The Hague?)

#### Landscape.

Snow seems to be coming thicker and faster among the landscapes, and most of the pieces have tree-trunks and sunshine as accompaniment. One of the nicest of this order is Marie Ruge's "Im Grünewald" (No. 288), with its excellent effect of daylight, and not the least good is that of Paul Mühsam, "Schnee" (No. 16), with its fir trees and its strong side light from the sun. W. H. Evans's "Snow Bound" (No. 95) has a good sky and true tones. Curious and simple, but very good too, is L. D. Sweet's "Winter in the Country" (No. 102), and another version of the favourite subject is "Winter Sunshine" (No. 110), by J. J. Rutherford. The President's "Winter Landscape" (No. 123) is hard to match among the best of them. It gives the snow-covered margin of a pool, with a distance of dark trees and farm buildings, and is very rich and varied in its tones. Dr. C. Thurstan Holland sends his fine and impressive "Head of the Valpelline" (No. 226), a convincing and vigorous Alpine view. Again sunlight on the snow appears as the subject of "Wintersonne" (No. 295), perfectly good and true, by J. Steidel, whilst Dr. Kühfahl's "Winter in Riesengebirge" (No. 309) shows in an expansive and expressive scene how the snow, drifting against the stunted firs, makes white hummocks of them.

Less forbidding subjects are A. H. Piddington's exquisite little "River in its Childhood," (No. 28), a shaded stream with children upon its banks; "Crépuscule," by F. de Thierry; another "Crépuscule" (No. 51), by L. Missonne; and G. Bowley's "Dying Day" (No. 53), a little thing of choice quality and much romance.

"Die Nonnen" (No. 41) belongs to that new phase of landscape art which is best described as Modern German, the characteristics of which are great breadth of treatment, a certain wildness or baldness in the subject matter, and a strong romantic feeling. Paul Mühsam's "Nuns" is touched with all this. The women are on the edge of

ground against the sky, across which cut the stems of large in the foreground. Everything but the sky is in almost flat ouette. Of the same school really belongs "Sommerlandschaft" (No. 118), by A. Meyer, although it is neither dark nor flat: but its simple lines and impressive breadth give it the same look of originality. The clouds are curious in this. In O. Scharf's "Eichen" (No. 173) little more than the stems are shown, the work by its silent strength belonging to the same school still, as also does Dr. Arning's "Elegie" (No. 265), although this loses some exaltedness of reason of the feeble sky and by the introduction of two ladies in a day dress, the right-hand one of which had much better have been omitted in the interests of the composition. How much finer "Morgen" (No. 275) is, with its carts in the sun-laden fog of a wet. Here faithfulness to nature gives him the poetry that his "Elegie" lacks. The dignified "Cypressen" (No. 131) of Dr. Arning, with a peasant woman and children figure importantly, is not only pleasant in its hard lights upon a dark effect, though it is doubt true to strong sunshine among dark objects and in air so rare. The English view by R. G. Lynam, called "When Shadows lengthen" (No. 124), has a similarity in subject, but freedom from drawback.

In the "Wilderness" (No. 144), by Arthur Elliott, is at the opposite pole to the modern German style. It is not "treated," but, on the contrary, it contents itself with being realistic. The result is that it appeals to the same sensibilities in us, though by a different method. There are few things in the gallery more realistic and yet so impressive and poetic. It is a deep ravine, the sides of which are covered with woods reaching down to a still lake below. From the zenith come the clear rays of the sun, striking only upon the surface of things and showing all else black from lack of direct illumination. Observers of nature will be able to testify to the truth of the effect.

We welcome J. C. Warburg's "Bastide Among the Olives" (No. 100) as an ambitious attempt on his part, which will certainly enhance his reputation. Its picturesque stems have much in common with the modern German feeling for such pictorial items. We think the print would have gained had the house been in darker tone. English is Rev. H. W. Dick's highly pleasing "River at Rest" (No. 90), although its evening effect seems, judging by the smothered light, to be due more to extraneous darkening than to an exposure made at late evening; but opinion is risky on such points. In style of appearance "A Sunny Glade" (No. 147) is not unlike some of

the popular architectural subjects that Mr. Kimber gives us. He has a little over-balanced his sun with shade and falsified his title, which might better have been "A Shady Glade." We confess to a feeling of getting used to the sweet conventionalities of C. F. Stuart. We still admire them, and admit all the beauties of his very charming "Chill October" (No. 196). But the strong family likeness it bears to its forerunners induces us to think that Mr. Stuart may be too rapidly developing a mannerism in his work. Mr. Bertram Park's delightful little stream (No. 202), shaded by willows, is quite unsophisticated, and its shady effect, wherein one can almost feel the green light that filters through the trees, exalts it into the highest rank of landscape. F. de Thierry's "Nuit d'Été" (No. 252) is a tiny and romantic print that reminds of an early Demachy. About the landscapes of B. Ward-Thomson we have mixed feelings. His love of the subjects he portrays is evident, but he is perhaps too jealous of losing a particle here and there. As a consequence he rather damages them by over-hardness at the edges of the hills. On this account we much prefer "Patterdale" (No. 258) to "The Cumberland Hills" (No. 219). The former has some charming passages. In "Ein Sommernachmittag" (No. 264) A. Erdmann gives us with startling truth the sunny aspect of a summer's afternoon; tone values could hardly of themselves be made to express more. Unfortunately the clouds in the sky are so hard as to look almost like Alpine peaks. "Grünwaldsee" (246), another of Miss Ruge's works, very cleverly deals with a rushy pool at the edge of which grow birches. She has imbued the whole with nice poetic feeling. "A l'Eau" (No. 239) is again more realistic, but excellently done by M. Missonne, who has quite conveyed the beauty of the effect of the cattle in sunlight and the perspective of their shadows.

In John M. Whitehead we have another clever worker who seems likely to drop into mere mannerism. All the nice things he shows this year at either gallery are as like as peas to each other. His "Moonrise" (No. 285) has great feeling, and his "Silent Moor" (No. 119) romance. We hope he will go back occasionally to his excellent still-life work. Dr. Evershed's "Wayfarers" (No. 304) are a flock of geese, represented, by the oil-process apparently, with much skill and liveliness. Perhaps the background has been allowed too much nebulousity. This and James Shaw's "The Captain's Horse" (No. 138), a clever result from a Rothenburg pageant snapshot, are the only pictures in the exhibition that can be at a pinch classified as animal subjects. Animals and architecture are a little "slumped" this year.

## THE TECHNICAL SECTION.

It can hardly be said that the technical section is satisfactory. Probably it is inevitable that one should have this year so many bits of the same type as last year. Certainly, with the exception of the Martian photographs and the Autochromes, there is nothing particularly striking. The exhibits naturally fall into two groups, the largest of which is that devoted to natural history subjects. We will, however, as befits the present interest in colour processes, treat first of the colour work.

The Judges and Selection Committee in this section were Messrs. J. Bolas and Chapman Jones, Dr. C. E. Kenneth Mees, Mr. E. J. Shepherd, Sir Joseph Swan, Mr. E. J. Wall, and Major-General Waterhouse.

### Colour Work and Autochromes.

It is unfortunate that the examples of colour photography should be scattered in different parts of the exhibition—the paper prints at the extreme end of the balcony and the examples by the Sanger-Shepherd process among the lantern slides in the north room. A comparison of the different classes of colour work, which could only have been made possible, thus involves journeying from one of the New Galleries to the other, and even then the totally different illumination of the Autochrome and Sanger-Shepherd results make it impossible to form an idea of their relative brilliancy. Among the prints Mr. Comley's exhibit is easily first, one or two of most excellent. Mr. Gill also sends one or two examples of the first-rate work.

Coming to the Autochromes, there is no doubt that the collection includes some remarkably successful work, though about one-third of the transparencies are so placed in relation to the reflecting screen, or are not in relation to it, that they cannot, or could not when seen a day or two ago, be properly seen by persons of

average height. The reflectors are not carried out far enough, and lights on the other side of the fountain court are visible through the transparencies. The receiving chamber, in which spectators observe the pictures, receives absolutely no light, except that coming through the transparencies, so that the gain in brilliancy of the Autochromes is obtained at the sacrifice of convenience in finding the number on each. A prominent though occasional writer on photographic art was overheard to remark: "The Autochromes are fine, but you want a lighthouse to show them." The R.P.S. has done its very best to enhance the qualities of the new transparencies and shirked the comparison of them with other processes. Its obvious duty as an educational body should have been to render such comparison as full and as convenient as possible. Yet the attitude of the Society, as further evidenced by a poster which it displays on the doorway of the New Gallery—and, for all we know, elsewhere—seems to be that of a boomster on the platform of a booth inviting the great British public to come in and see a side-show of unrivalled interest. Not a particularly dignified attitude for the Royal Photographic Society.

The best of the Autochromes are, we think, the portraits of the President of the R.P.S. and Mr. John Sterry, by R. Child Bayley; and a study of some books. Mr. McIntosh's spectra are very interesting, but quite wrong. If this be the fault of the plates—we are not prepared to say it is—it shows the limits of their capabilities. Particularly striking is the want of true red-sensitiveness (the red does not appear to extend beyond about  $\lambda$  6,500), the entire absence of pure yellow, and the lack of blue. Certainly, in the arc spectra, we think that in some cases the failure is due to errors in exposure.

Two specimen plates and a yellow filter are shown by MM. Lumière, and the plate deservedly receives a medal. The exhibits as a

whole include some really beautiful examples of colour rendering, the truth of which is, however, not invariably apparent; whilst not a few examples are obviously false in their colouring. One or two stereo-Autochromes available for inspection outside the gallery show very brilliant colouring, but demonstrate also the distressing granular and pattern effects which result when a stereoscopic transparency is examined.

### Natural History Photographs.

Most prominent in the technical section are Mr. Douglas English's exhibits, because of the very striking and successful attempt to show the animal or insect in as far as possible facsimile as regards colour. They are not three-colour prints, but have been merely locally treated, in the case of two, at any rate, with mercury and ammonia. With what success this can be done is easily seen by comparing the actual skin of the mouse with the print, the skin being in a pouch at the back of the frame, No. 318. The two insectivorous studies by the same worker are so successful that doubtless we shall have imitators next year.

Possibly the most interesting, at any rate from the ornithologist's point of view, are Nos. 330 and 333, the former by Miss E. L. Turner, showing the decidedly rare Reeve, and the latter the Bearded Tit, by Mr. W. Farren.

Mr. G. A. Booth's heron studies are also good, but he is run very close by A. Taylor, whose print, No. 345, has a fine decorative effect. Other exhibits of this class do not call for much particular notice. There is, as we have already pointed out, a great similarity to prints in last year's show.

### Nature Studies.

We may thus comprehensively class all the creeping and other beasties, such as Mr. Martin Duncan's "Larvæ of Privet Hawk Moth," his Crab, and other studies, which display the excellence of technique for which he is famous. Mr. Douglas English's life history of the mud wasp is of considerable educational value. Mrs. Veley is happy in her studies of the restless Lemur, and the fair visitors will naturally admire Mrs. H. C. Sutherland's "Persian Kittens."

As to plant studies, Mr. Daniel Finlayson is easily first with his three frames, which are very educational and a good example of the application of photography to a fruitful field. The same may also be said of Mr. A. W. Dennis's frame, which shows a year's life of the common walnut tree. Of the other flower studies one can only say that they are just passable, there is nothing of striking merit.

## PROFESSIONAL AND TRADE EXHIBITS AT THE R.P.S.

Pressure on our columns this week compels us reluctantly to hold over a notice of this section of the exhibition until next week.

### THE CHOICE OF LENSES.

(From the new Goetz Catalogue.)

THE following hints on the choice of lenses may be found useful:—

The single combinations of the "Dagor," when stopped down, form admirable long-focus lenses. The value of the stop is one-half of that indicated by the diaphragm, and the intensity one-fourth, i.e., if the single combination is employed and the diaphragm is stopped to  $f/16$ , the stop in use is  $f/32$ , requiring four times the exposure of the former.

Under less favourable conditions of light the "Celor" may be used with advantage, as their rapidity is double that of the "Dagor." Hence they are eminently suitable for indoor portraiture, for snapshots, and for telephotography.

The photographer is cautioned against using the full aperture ( $f/4.8$ ) for views requiring great depth of focus, such as street scenes, landscapes, etc.

"Depth of focus," so little understood, is the capability of a lens to render objects at various distances from the camera with sufficient sharpness. This is governed by optical laws which are unchangeable, and is not the attribute of any special form of lens. The more rapid the objective, i.e., the larger the aperture in proportion to length of focus, the less is the depth of definition; the slower the lens the greater is the depth. In lenses of the same rapidity, but of varying foci, the greatest depth will be given by the shortest focus.

With such a large aperture as  $f/4.8$  the depth of focus is very

### Photomicrographs and Radiographs.

Probably the most interesting photomicrographs are those Messrs. Lynch, of "the human hair, with its sebaceous glands," which illustrate the absolute falsity of many advertisements appearing in the public Press.

Particular notice should be taken of Mr. Martin-Duncan's photomicrographs of living bacteria. The results are totally different from those one is accustomed to see of bacteria killed with acids or other reagents. When examined with a glass one can actually see the structure of these minute organisms.

### Spectra, Cloud, and Astronomical Work.

Particularly interesting are Mr. K. J. Tarrant's artificial light studies. These should go far to help us to learn more of the nature of real lightning. Professor Konen's spectra of iron cyanogen are superb in definition, but the prints are far surpassed by his transparencies shown under the lantern stand. Sir V. Huggin's spectrum of the glow of radium is excellent. The cloud studies by J. Howden Willie are good.

One of the only two medals awarded goes to Professors Loew and Lampland for the Martian photographs, and these should be very carefully examined, not only on account of the famous canals but also for the very clear view of the polar cap. Dr. Vaughan Cornish's studies of the Kingston earthquake show in a very striking manner the effects of this awful visitation, but the notes appended in the catalogue are rather meagre.

There are many other good things shown, but one of the most interesting is a specimen of the new "bromoil" process by C. V. borne Piper, which should bid fair to become a popular and effective method of pigment printing. The colour reproductions by H. Staengel are worth noting.

### Lantern Slides and Transparencies.

There is but a meagre show of these, but they are most of the highest merit, and we should give the palm to a portrait by Sanger-Shepherd three-colour process, by A. W. Everest. In this section one must not omit to note also Professor Lowell's transparencies of Mars, and Dr. Homolka's set, showing the use of indoxyl and thioindoxyl, full particulars of which have appeared in the "B.J.P." The architectural work of Messrs. Bull and Plomer Young is excellent, as are also Mr. Ellis Kelsey's slides.

Those interested in spectroscopic work should make a point of seeing Mr. F. E. Ives' grating replicas.

limited, and at this intensity some part or other of a general view must of necessity be blurred, unless it can be taken from a considerable elevation so as to cut off a great extent of foreground. The legitimate use of such a lens as the "Celor" at full aperture is therefore, for subjects that require little depth, i.e., where all essential objects in the field of view are approximately the same distance from the camera.

It must not be forgotten, however, that unlimited depth of focus may be introduced by stopping down the lens sufficiently, and that the "Celor" and the "Dagor" have precisely the same depth of focus at the same intensity.

The  $f/8$  aperture is a valuable adjunct to hold in reserve for suitable subjects, and the photographer has only himself to blame for failure if he uses this indiscriminately.

The foci recommended for the various sizes of plates in the following lists are those which will be found most generally useful when one lens only is used for all purposes. For interiors and other wide-angle views, a shorter focus must be selected (unless the same lens is used with a larger camera); but in some cases it may be advisable to employ a longer focus, when the main object is to obtain as natural a perspective as possible.

All lenses transmit the greatest intensity of light to the centre of the negative. Over an angle of 60 deg. there is scarcely any perceptible difference, but as we approach 90 deg. the inequality becomes more apparent. This defect can only be remedied by using a smaller stop.

## DEATH OF MR. WILLIAM HARDY KENT.

MR. WILLIAM HARDY KENT, who was regarded as the oldest photographer in the world, died at Eastbourne on Sunday last, aged eighty-eight. An American by birth, he spent his early years in New Bedford, Massachusetts. Five or seven years after Daguerre's invention, Mr. Kent learned the art of photography, and in 1848 he opened his first studio in New York.

So great was his success that after realising a small fortune he came to England in 1854 and opened three London studios—one in Oxford Street, one in Regent Street, and the other at Knightsbridge. He had an intimate knowledge of the improvements successively introduced into photography, but for a time devoted his attention to a manufacturing business. A change in fashion induced him to return to his first occupation, and in 1878 he opened a business in Eastbourne. At the time of his death he was also interested in businesses at Brighton, Hastings, Newcastle, and Harrogate. He retained his mental faculties to the last, and only recently manifested a deep interest in a new method of photographic portraiture.

Mr. Kent was a constant traveller to the States, having crossed twenty-nine times, the last occasion being at age eighty-five, when, quite alone, he made a tour of four months' duration. He has not controlled the business of Kent and Lacey, at Eastbourne, for the past seven or eight years, though he took a keen interest in all its affairs and every new development.

## Photo-Mechanical Notes.

## Made-ready Printing Blocks.

A SPECIFICATION has been published of a patent of William Bell and Harry Bryce Bell, of Cowles Road, Mosman, New South Wales, in which the claim is for producing an embossed etched plate for half-tone printing, by printing the face of the plate, supporting the back of the plate below the "blacks," pressing the plate to sink the surface in the "high-lights," and finally etching the embossed face. The specification, No. 27,529, 1906, thus describes the process:—

The production of the printing block entails the treatment, in one instance, of both surfaces of the plate; in another, of one surface only of two metal plates; and in a third, the treatment of one metal plate and one gelatine sheet. That surface, which is ultimately used as the printing surface, is here referred to as the "face," and the other, which is not used for printing, is referred to as the "back."

In referring to the operation in which both surfaces of the plate are treated, a photographic negative of the object to be reproduced is taken in the ordinary way through the usual lined, Levy, Metzograph, or other similar screen. The negative is then stripped on to a thin celluloid film, and allowed to dry thereon. The metal plate—preferably copper or zinc—which is to be used for the production of the block, is sensitised upon its "back" with any of the well-known sensitising solutions, preferably fish glue and bichromate of potash or ammonia, and a print is then taken upon it from the celluloid mounted filament by placing the celluloid "face" thereof in contact with the sensitised surface of the metal in a printing frame, and exposing it to light in the usual way. The "back" of the plate is then developed—namely, washed in water, soaked in an aniline dye, the soluble glue washed out, and the print upon it "burnt in." The plate is then placed in a mordant or acid bath, and the "back" thereof deeply etched for a period of time sufficient to secure the required weakening of the plate upon those portions representing the "high-lights" and "half-tones," the face meanwhile being protected by being coated with an acid resisting substance or material. In this part of the operation very little skill is required to effect the correct etching. The plate is withdrawn from the bath when the required depth has been obtained. The "face" is sensitised, and a print taken upon it from the same celluloid backed negative. In this case, however, the collodion film on the celluloid mounting is placed in contact with the "face" of the plate. Care must be exercised in the placing of the film on the "face," so as to ensure the accurately registering or coinciding of the prints on the back and front of the plate. The "face" is then developed, the print "burnt in," and the plate, whilst still hot, placed upon a hard metal slab

in a pressure press, with its deeply etched surface or "back" resting upon the slab, and a sheet of lead placed upon its upper surface or "face." Sufficient pressure is then applied through the lead sheet to cause the thinned or weakened portions to be forced downward to a degree corresponding to the amount of the weakening the plate had been subjected to at these parts; thus those portions which represent the "high-lights" or "whites," and which have been most deeply etched, are forced downward the most, whereas those representing the "half" or "middle" tones do not sink so far; whilst those portions representing the darker shades or blacks do not compress. Should the plate be allowed to cool after the "burning-in" process is completed it may be re-heated to soften it prior to embossing it in the press. Should it be found inconvenient, however, to submit the plate to pressure whilst hot, this operation may be carried out when it has cooled, in which case a sheet of gutta-percha, leather, or lead may be used to effect compression in the pressure press. Greater pressure, however, is required in this case. The "face" or printing surface of the plate when removed from the press presents an embossed surface. It is then subjected to the action of a mordant or acid bath to etch the "face," the "back" meanwhile being protected by an acid resist. Owing to its embossed surface the plate requires comparatively little fine etching to produce a clean, sharp printing surface, thus the time at present employed to effect the fine etching of a "half-tone" plate is reduced.

The plate is now ready for "proving," and is mounted in the usual manner.

## PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—

SCREENS.—No. 18,957. Improvements in ruled screens for process engraving. John J. Griffin and Sons, Ltd., and William Joseph Holt, 322, High Holborn, London.

GUIDING APPARATUS.—No. 19,408. Arrangement for guiding off the printing material in photographic printing apparatus, with apron and rotatory printing cylinder. Hans Viggo Siim, 65, Chancery Lane, London.

## New Materials.

The Page-Croft Tinted Gaslight Papers. Made by the Page-Croft Paper Company, Cooksey Road, Birmingham.

It was not very long ago that we were able to review favourably the tinted P.O.P. papers and postcards which had been placed on the market by Mr. Page-Croft's firm. On their now sending us some samples of gaslight paper, coated on some similarly tinted supports, we are glad to find that the makers have exercised a similar reserve in using a paper stock of not too pronounced a tint. The papers are obtainable of tints—grey, pale green, pale blue, and pale pink, and the effects obtainable by the ordinary procedure of gaslight printing should be very acceptable to those who are looking for a variation from the usual results. In all ordinary respects the papers are treated like any other gaslight prints, and are amenable to the sepia toning by the sulphide process, which renders possible a further variation in the contrast of tones. We are glad to draw attention to this further departure on the part of Mr. Page-Croft's firm, particularly as there are but few tinted papers of this description upon the market. The tinted gaslight papers are issued at the ordinary prices.

TWO ARTICLES which should be read with special interest in the current issue of the "Strand Magazine" are "Up-to-date Telephotography," by Captain Owen Wheeler, who also recorded his experiments in our issue of September 27, and "Beauty and the Camera," an article with numerous illustrations, which should appeal to all portrait photographers.

PHOTO-APPARATUS IN BELGIUM.—The "Board of Trade Journal" reports that folding and pocket cameras are popular in Belgium, and are in considerable demand. All accessories, such as plates, films, printing papers, etc., of British make have a good sale, but Continental sizes predominate, and it is of little use for British firms to endeavour to sell the sizes used in the United Kingdom.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between September 16 and September 21:—

**PRINTING PAPERS.**—No. 20,641. Adhesive coating for photographic printing papers; also for single or double transfer paper, or final support, for use in conjunction with carbon printing or other photographic printing processes. George Wilson Morgan, 393, Union Street, Aberdeen.

**LENS' HOODS.**—No. 20,706. Improvements in hoods for photographic lenses. Owen Wheeler, "Strathmore," Prince's Road, Weybridge, Surrey.

**EMULSION.**—No. 20,740. Improved photographic emulsion for pigment printing. Jacques Theodore Gateau, 2, Boulevard Beaumarchais, Paris.

**ENLARGING.**—No. 20,940. Improvements relating to photographic copying, enlarging, and like apparatus. Alchanan Cohen, 53, Chancery Lane, London.

**CAMERAS.**—No. 20,989. Improvements in folding cameras. Cranley Lancelot Perry, 73, Cheapside, London, for Emil Wünsche Aktienges., für Photographische Industrie, Germany.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**GLAZING PRINTS.**—No. 38,811. 1906. The invention consists in the burnishing or glazing of photographic prints by a machine, which consists of a travelling plate or table, and an adjustable pressure roller adapted to revolve as the plate travels; this roller is preferably hollow, and may be heated by a Bunsen gas burner or other suitable means. When the photograph is treated by a heated roller it is placed face upwards on the plate or table, and when treated cold it is placed face down on the plate or table. The plate or table is caused to travel under the pressure roller by any suitable means, and takes the print with it, and the print is burnished or glazed, as the case may be, by the act of passing to and fro under the pressure roller, the pressure of the roller being adjusted to suit either unmounted or mounted photographic prints. James Thomas Eltringham, 23, Portsmouth Road, Worlston, Southampton.

**VIGNETTING BOX.**—No. 25,880. 1906. The apparatus comprises a box *a*, open at one of its extremities *b*, to permit of inserting a printing frame *c*, which is shown in broken lines, whilst it is closed at its other extremity by a frame *d*, carrying two ground glasses *e* and a dark shutter *f*, capable of sliding between these two glasses.

Two screen or mask holders are fitted in the box *a*, one of them, *g*, being fixed to a small plate *h*, which rests on the bottom *i* of the box, and the other *k*, being fixed to a small plate *l*, likewise resting on the bottom *i*; the two plates, *h* and *l*, are each of about the same width as half the width of the bottom *i* of the box, and in sliding on this bottom enable the screen holders *g* and *k* to be advanced or withdrawn relatively to the ground glasses *e*; a flat spring *m* fixed to the side *n* of the box *a* constantly bears against one side of the plate *l*, a set screw *o*, which is screwed into the side *n* enabling the two plates *l* and *h* to be fixed when the screen holders are arranged at the appropriate place.

The screen holders are each formed of a plate *g* *k*, open at *p*, and to the sides of which there are pivoted metal plates *q* *r*, forming springs, and intended to hold against the plates the screens, which are generally of black paper, their aperture being of an appropriate form for obtaining the desired vignetting of the prints. The strips *q* pivoted at *s* to the plate *k* may be engaged beneath catches *t* screwed on to the plate, and the strips *r* pivoted at *u* on the plate *g* may be engaged beneath catches *v* screwed to this plate.

The vignetter may be used in the following manner:—

The front of the apparatus carrying the ground glass *e* is placed in front of a lantern, not shown in the drawing, containing a source of artificial light, such, for example, as a electric lamp,

a gas burner, or the like, in such a manner that no ray of actinic light issues from the lantern or from the joint between this lantern and the front of the vignetter.

The dark shutter *f* being opened, the negative plate arranged in the printing frame *c* is focussed by moving forward or back-

Fig. 1.

Fig. 2.

ward, or to a greater or less extent, one or other, or both the two plates *h* and *l* solid with the screen holders *g* and *k*, until the desired vignetting effect is observed upon the plate. The shutter *f* is then closed, the sensitive paper is placed upon the negative plate, the plate-holder *c* of which is arranged as represented in Fig. 2.

The plate is then exposed in contact with the sensitive paper by opening the shutter *f* for the desired length of time, the shutter is closed, and the operation is repeated as many times as it is desired to obtain positive prints. Philémon Makeeff, 26, Rue de la France, Le Locle, Switzerland.

### New Trade Names.

**ERROR.**—No. 293,546. Photographic developers. The Chemische Fabrik auf Actien (vorm. E. Schering), 170, Müllerstrasse, Berlin, manufacturers. June 6, 1907.

OTOPHANE.—No. 295,381. Printed matter produced by the colotype process. Alfred Henry Cooper, trading as the Photophane Company, Cranfield Works, Harefield Mews, Brockley, Kent, colotype printer. August 9, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### How to Overcome Frilling of Autochrome Plates.

The "Amateur Photographer," in its issue of Tuesday last, publishes among its weekly notes on colour photography the following hints on the avoidance of the frilling prevalent among autochrome plates. Our contemporary's other paragraphs on the recent advances in colour photography are deserving of a careful reading, and we may refer our readers to its regular page, "Colour and the Photograph," for the announcement, among other matters, of still other "colour-screen plate." The writer says: "Our earlier series comparative experiments on the use of the various modifications formula for the F solution were considerably disturbed by frilling, this being more particularly the case with the two modifications of F solution, in which citric acid is used in the proportion of grammes to the litre, but by adopting the following course we have completely overcome the tendency to frill, and this without the aid of any impervious or waterproof edging; at any rate, there has been the slightest indication of frilling since we have adopted the following course, and in illustration of this we may refer to the sets of four plates now on view at our office, as illustrating the various prescriptions for intensifying. Although the plates used were cut from larger sizes and no edging was used, the film is perfect and unfrilled up to the extreme edge in every case. Careful comparative trials showed that no disadvantage followed the course now recommended. After the use of the C solution (acid permanganate), and rinsing during about forty seconds, the celluloid strainer bearing the plate or plates was immersed in a 3 per cent. solution of purest recrystallised chrome alum (Hopkins and Williams), not the impure commercial chrome alum obtained as a residual product in oxidising aniline colour materials. In this bath the plates were allowed to remain for ten minutes, the celluloid strainer being lifted occasionally. The plates were then washed for five minutes, the celluloid strainer being kept in constant motion up and down in changes of water, and now the D solution was used in the ordinary way, and after its use and a slight rinsing the celluloid strainer was placed in a 1 to 6 formalin bath and allowed to remain for five minutes. Then, after a washing of forty to sixty seconds the E solution was used and the plates rinsed. Now there was another immersion for five minutes in the formalin bath, followed by washing and intensification. Similarly the plate was immersed in the formalin bath before and after the use of the H solution, thorough rinsings being resorted to to avoid mixing the solutions.

### CATALOGUES AND TRADE NOTICES.

MR. J. LIZARS has issued an illustrated catalogue, which deals chiefly with the latest addition to and improvements in his well-known "Challenge" cameras, and in order that any one still unacquainted with these cameras should speedily remedy that defect Mr. Lizars makes a special offer of an "advertisement outfit" at a considerably reduced price. Other specialties manufactured by the same firm are also dealt with in the latter portion of the list, which may be obtained by any of our readers on applying to Mr. Lizars, 101, Buchanan Street, Glasgow.

HULL PHOTOGRAPHIC SOCIETY.—The members of this society have contributed the sum of £12 10s. to the Selby Abbey Restoration Fund. THE HON. JOHN COLLIER is exhibiting his important picture, "Lady Godiva," at the Modern Gallery, 61, New Bond Street, W., for a few weeks.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### MONDAY, OCTOBER 7.

Southampton Camera Club. Slide Criticism.  
South London Photographic Society. "Portraiture." Mr. Harold Baker.  
Bradford Photographic Society. "Ideas on Exposure and Development." J. F. Seaman.  
Lancaster Photographic Society. "Carbograph." Rotary Photograph Company, Ltd.

#### TUESDAY, OCTOBER 8.

Keighley and District Photographic Society. "The Land of Carillons, Canals and Coifs." Chas. B. Howdill, A.R.I.B.A.

#### WEDNESDAY, OCTOBER 9.

Worthing Camera Club. Outing to Angmering and Decoy Ponds.  
Everton Camera Club. Photographic News Prize and Members' Slides.  
Croydon Camera Club. "The Oil Printing Process." J. J. Griffin & Sons.  
Birmingham Photographic Society. "Marine Photography." F. J. Mortimer, F.R.P.S.  
Coventry Photographic Club. Exhibition of R.P.S. Affiliation (1907) Prize Prints, also Autochrome Pictures.  
Leeds Camera Club. "Control in Simple Combination Printing on Bromide Paper for Pictorial Effect." Harold G. Grainger.  
South Suburban Photographic Society. "Points for Picture Makers." H. Snowden Ward, F.R.P.S.

#### THURSDAY, OCTOBER 10.

Richmond Camera Club. "Home Portraiture." P. G. Payne.  
Liverpool Amateur Photographic Association. "Black and White Art." E. Rimbaud Biddin.  
North London Photographic Society. "Possibilities of Autochrome Plates." C. H. Madden.  
Wimbledon and District Camera Club. "What Can be Done with a Hand Camera." C. P. Goerz.  
Hantsworth Photographic Society. "Tentative Development." F. Holloway.  
London and Provincial Photographic Association. "Flower Photography." E. Seymour.

## Commercial & Legal Intelligence.

"PROCESS" DIRECTOR'S BANKRUPTCY.—The Official Receiver, in the Bankruptcy Division of the High Court, has now issued particulars under the failure of Thomas William Lascelles, photo-mechanical etcher, and director of Lascelles and Co., Ltd., from which it appears that the debtor has filed a statement of affairs showing unsecured liabilities amounting to £225 0s. 6d., and assets nil.

The report and observations of the Official Receiver are to the following effect:—The receiving order was made on a creditor's petition, the act of bankruptcy being non-compliance with the requirements of a bankruptcy notice. The adjourned first meeting of creditors was held on September 5, when no resolution was passed. It appears from the debtor's statements that he has been for the past eight years, and still is, the managing director of Lascelles and Co., Ltd., photo-mechanical etchers, at a salary of £7 a week and 15 per cent. of the net profits; that he is a director of two other companies, from each of which he receives £25 a year, and that his income up to three years ago amounted to about £1,000 a year; but owing to decrease of profits it has since been about £500 a year, out of which he has had to pay £100 a year for travelling and other expenses. The debtor attributes his failure to liability in respect of rent and dilapidations of a house, which he took on lease at £95 a year, and which, owing to the decrease in his income, he had to vacate some years ago. The unsecured liabilities include £6 13s. 6d. for goods supplied, and £52 5s., the amount of a judgment obtained for rent to September, 1906, of the house mentioned above. The "other liabilities" include £71 5s. for three quarters' rent of the house to June, 1907, and £95, the amount estimated to be due for dilapidations. The debtor states that he sold his furniture shortly after he left his house.

UNLAWFUL POSSESSION.—Samuel Wiltshire, aged 20, and William Gaskell, aged 50, two rather rough-looking customers, when met by Detective Mullins last week in High Street, Brentford, carrying a valuable camera, were asked how it came into their possession. Samuel replied that his uncle had made him a present of the instrument that very afternoon, and he was taking it to a Brentford photographer in order to try to effect a sale. The detective

appearing doubtful, William seems to have thought that the story needed reconstruction, for he is alleged to have said that he himself had bought the camera some time previously in a lumber room. The detective was here faced with the delicate task of deciding which of these stories, if either, was correct, and he decided to shift the responsibility on to the local Bench. Even their Worships, however, failed to decide the question offhand, and after hearing the evidence they remanded Samuel and William on the charge of unlawful possession.

## News and Notes.

**THE NEW GOERZ CATALOGUE.**—In its handsome cover, embodying a design by Mr. Eduard Steichen, the new catalogue of the firm of C. P. Goerz, is a notable publication of the greatest interest to all photographers studying that most important part of their outfit—the lens. Messrs. Goerz believe in doing everything well, and the production of their list is but in keeping with their sustained performance as opticians, which is only to say that it represents a standard of efficiency and excellence not easily surpassed. The list first of all explains very succinctly the principles to be borne in mind when selecting a photographic lens, the matter of which appears to us to be so precisely to the point that we quote most of it on another page, though certain of the paragraphs lose something from their withdrawal from the context. The list portion proper of the publication enumerates the various series of Goerz lenses, with notes in each case on the purposes for which the lens is chiefly fitted, and on the facilities provided in the way of sub-division into two or more instruments, and in other respects. Accompanying these particulars, which, by the way, are very clearly printed, are a series of half-tone reproductions representing some highly technical and critical work done with the Goerz instruments. There is also a frontispiece on Wellington carbon-surface bromide paper, showing the fine definition to the corners of a plate afforded by a 6-in. "Dagor" (the 5 x 4 lens) on a whole-plate. The list is obtainable gratis from Messrs. Goerz at 4 and 5, Holborn Circus, W.C., and should be studied with interest by every photographer.

**PHOTOGRAPHIC SURVEY OF DUNDEE.**—Dundee has been placed under great obligations to the Dundee and East of Scotland Photographic Association for the exhaustive work undertaken by the members to produce a historical photographic record of the city. In the latter half of the nineteenth century Dundee, thanks to municipal enterprise was transformed from an old-fashioned town, with narrow streets and tumble-down buildings, into a modern city, with wide thoroughfares and handsome blocks of property. But the great change was not accomplished without the demolition of buildings of some historical significance. During the past four years of the association in making the photographic survey, in that time about 2,000 prints have been obtained, and the work is not yet completed. The labour has obtained an incentive through grants from the Town Council, although the money does not by any means represent the labour and cost of the extensive operations. Last week the public for the first time had an opportunity of witnessing the results of the society's effort, the prints having been hung in two of the galleries of the Albert Institute, constituting one of the most unique and interesting exhibitions Dundee has had for a considerable time past. The work produced is very varied in character, the exhibition being a pictorial record of what Dundee is to-day, regard being given to public buildings of all kinds, industrial activities, municipal enterprise, and the life generally of the people in their employment, leisure, and pastimes. There are also many street scenes and river views, and a military section. A proportion of the prints are taken from negatives obtained forty years ago, these portraying bits of the city which have since passed away. After the exhibition closes a complete set of the prints will be made up into books, and placed in the Albert Institute for the use of the public, while a duplicate set will be handed over to the custody of the Town Council for preservation in the city repositories. Attached to many of the prints is descriptive literary matter, and this will in time be completed so far as is necessary. This section of the work has been undertaken by, among others, Mr. John Macdonald, Mr. A. H. Millar, Mr. Alex. Hutcheson, Mr.

T. S. Robertson, Professor Steggall, ex-Councillor Elliot, and Dr. Templeman, and the entire survey has been organised and supervised by Mr. O. B. Hatch, the secretary of the society.

VISITORS to the exhibition of the Society of Colour Photographers at the house of the "British Journal" were no doubt grateful for the enterprise which gave rise to the presence, at the edge of the

footway, of a street merchant from whom they were able to purchase copies of a manual entitled "Real Colour Photography," which we understand has been issued by a contemporary. The photograph here reproduced was taken on Wednesday afternoon.

## Correspondence.

### AUTOCHROME RESULTS AT THE R.P.S.

To the Editors.

Gentlemen,—I am receiving many inquiries about the autochrome photographs in natural colours now on view at the Royal Photographic Society's Exhibition at the New Gallery, 121, Regent Street, W., and shall be much obliged if you will publish this letter by way of answer.

The autochrome pictures in the balcony are on view all day, from 10 a.m. till 6 p.m., and also in the evening on Mondays, Thursdays, and Saturdays, from 7 till 10 p.m.

In addition, a number of autochrome pictures are exhibited by the optical lantern daily, in a darkened enclosure, near to the South Room, from 11 a.m. till 1 p.m., and from 3 till 6 p.m. at frequent intervals, when brief descriptions of the process are given. These lantern displays are also given on Monday, Thursday, and Saturday evenings before and after the advertised lectures.

To relieve the anxiety of those who have contributed transparencies to the colour section, I desire to say that none of these are shown by the lantern. Those so shown are a special set made for that purpose.

It may interest exhibitors and your readers generally to know that the number of visitors to the gallery is much in excess of last year, the actual numbers for 1906, to Thursday, September 27, being 2,722; and for 1907, to Thursday, the 26th inst., 4,220.—I am, yours faithfully,

J. MCINTOSH, Secretary.

The Royal Photographic Society of Great Britain, 66, Russell Square, London, W.C.

September 27, 1907.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Sargent, 12, Albany Road, Cardiff. Photograph of Mr. Will Crooks, M.P. Calhoun, 124, St. Domingo Vale, Anfield, Liverpool. Photograph of an actress on Deck of the Ship "Scottish Hills."

Perkoff, 188, Commercial Road, London, E. Photograph of Mr. Isador Epstein.

Blackburn, 43, Revidge Road, Blackburn. Photograph of the Blackburn Rovers Football Team and Directors.

Tom Thomas Whiffin, 770, Harrow Road, Willesden, N.W. Photograph of Queen's Park Rangers Football Team with Directors.

W. H. Redcliffe, Harpenden, Herts. Photograph of Mr. H. Steers as a knight.

ENLARGED NEGATIVES.—I shall be much obliged if you will advise me how best to make enlarged negatives with the least possible loss of quality. It suits my purpose (for working-up reasons) to make an enlarged positive, and from that to make my big negative. The latter I have been doing by contact. The enlarged positive I get as I want it, but then comes my trouble. The resulting negative therefrom is, in nine cases in ten, a great disappointment. It is woolly and lacks quality, no matter how I expose and how I develop. I use ordinary plates. Will you please tell me if I should do better with (i.) process plates, or (ii.) lantern plates, or (iii.) if I should do better still by making my big negative from the enlarged positive in the camera?—N. A.

We do not think you will find any advantage in using a lantern or process plate, supposing that at present you are not complaining of excessive or insufficient contrast. You will get a crisper negative by copying in the camera. The best work is done in this way, and on backed plates. Probably neglect of this latter is the cause of your trouble.

GOLD CHLORIDE.—(1) I should feel much obliged if you would kindly let me know the address of a firm who supply gold for making gold chloride. (2) Whether an apparatus made of brass and then silver-plated, and to contain a number of prints, could be used for washing, toning, fixing, and then again washing, by placing the apparatus in the different solutions? I should like to know if stains would result on prints, and if so, could you advise any other metal for the purpose?—J. T.

(1) Gold coins of the realm contain metallic gold of face value, and though, strictly speaking, it is illegal to use them for the purpose, there is no cheaper source of supply. (2) Most decidedly it will be unwise to use it, as silver is easily attacked by gold toning solutions. Only glass or porcelain should be employed.

TEMPER.—(1) Information as to the Warner-Powrie process plates will appear in due course. (2) As regards the "Autochrome plates," see our advertisement pages.

MERCURY VAPOUR LAMPS.—As I am about to buy a mercury vapour printing lamp, will you please let me know if, in the event of the mercury tube being broken whilst printing, the persons in the room are suffocated, having no chance to escape. I have been told that this is so, but I wish to obtain reliable information.—L. T.

There is no danger of the kind that is worth consideration. In the event of a lamp breaking, the mercury immediately condenses to the liquid state, in which form it can harm only metallic objects with which it remains in contact.

L. EDMUND.—Yes, "Aristo" is a registered name of the Kodak Company.

BROMIDE EMULSION.—Will you please give me, through the "British Journal," a formula for making bromide emulsion, suitable for matt surface, rapid bromide paper? Some years ago I made emulsions for paper, but have mislaid formulae, and fail to find such information in the "British Journal Almanac." I also wish to coat ground opal glass. Would the emulsion require more gelatine to prevent frilling, or is a coating of chrome alum and gelatine used, or would that make the emulsion too insoluble? I require the paper for enlarging by artificial light, and a paper that will give plenty of contrast and good blacks.—S. H.

We can best assist you by referring you to the book, "Photographic Plates and Papers," by Stiefel (Iliffe and Co.). The methods adopted in the making of modern bromide papers, which rarely frill, are not published.

BLACK AND WHITE DRAWINGS.—I should be glad if you can inform me what materials are required for working a black and white sketch for the press. Also what Indian ink or lamp-black and the best cardboard to use.—J. BURNS.

Get a good process Indian ink from Penrose and Co., or from an artists' dealer. Best white Bristol board, about as stout as the usual postcard, is the best.

PYRO-SODA DEVELOPER.—May I ask is there not an error in the formula of pyro-soda developer given on page 751 of the "B.J.," 1907? The quantities given show about 4 grains to the ounce of pyro, and 48 grains to the ounce of soda. Diluted with same quantity of water it would be about right.—JOHN A. D. LLOYD, Kodaikanal, Madras Presidency.

The formula is correctly stated. The larger proportion of pyro, in fact, general greater strength, is necessary to secure good density in a reasonable time. It can, of course, be mixed with an equal bulk of water, but will then be slower in action. We hope to obtain good keeping qualities and speed in one and the same solution, and our further results will be given in the "B.J."

GASLIGHT DEVELOPER.—Can you tell me, through your valuable journal, a good developer for gaslight postcards and paper, so as to get a good blue-black tone? What I am using now is metol hydroquinone. Sometimes the prints are all right, but the majority are rusty colour in the shadow, and if I under-expose they are green, so something must be wrong. I am most particular in mixing up the developer according to the formula.—PRINTER.

Any developer will behave as you describe if used improperly, that is, with too much bromide for the particular brand of paper.

We advise you to make one or two careful tests on the same negative with different exposures, and differing doses of bromide.

GENUINE PHOTOGRAPH.—Can you tell me if enclosed (which has been submitted to some rough tests) is a genuine photograph? I have an idea that it is a clever imitation made by some collotype process. If it is a recognised commercial product where can such work be obtained? They are being retailed here at 2d. each, and, I understand, are supplied wholesale at a lower rate than I insist on charging.—F. NEWELL.

The picture is a genuine photograph, and not a mechanical print. Thousands of such are retailed at 2d. each. The Rotary Photographic Company and similar firms will supply them.

REMOVING RETOUCHING MEDIUM.—Lately I had to reduce a negative which had been retouched. I have done this quite successfully at other times, but in this instance finger markings (made when putting on the medium) show. Can you tell me how to obliterate them? Retouching medium has no effect on them.—STAINS.

If the retouching medium does not remove the finger marks we should advise you to try turpentine. If that does not take them off try with benzol. One or other of these will no doubt clean the negative.

INTERNATIONAL COPYRIGHT.—Please let me know, through "Journal" correspondence, if the registration of a copyright in London covers me for British Isles only, and has anyone outside (for instance, Canada and United States) the liberty to copy for publication without any permission?—CARBON.

If the copyright in a photograph is registered in England it

is protected in all countries that subscribed to the Berne Convention. A list of the countries are given on page 677 of the "Almanac" for 1906. The United States do not subscribe to the Berne Convention, and the copyright is not protected there. As to Canada and some other British colonies, copyright law is somewhat lax, and protection under the International Convention does not amount to very much.

**RIGHT TO PUBLISH.**—(1) The enclosed view is taken from the high road. The people in the picture are making a great fuss because the cards are on public sale. When I took the view I had no knowledge who the people were. It was just an accidental picture. As the people are trying to bully me I should like to know if they can suppress the sale or demand the destruction of the plate. (2) If a lens cap is used clumsily and the lens is shaken would the definition suffer equally all over the picture or mostly at the outer edges? I use a cap with my W.A. lens, and at times get bad definition at the edges when the stopping down has been ample.—**CROSS ROADS.**

(1) The people certainly cannot restrain the sale of the postcards. They do not in any way hold them up to ridicule, and, moreover, the faces are so small and indistinct that no one would recognise them if they did not know who they were. (2) If the camera were moved in uncapping the lens the sharpness would be impaired all over the plate. The bad definition at the edges is probably due to the lens not covering properly.

**STUDIO QUERY.**—I am thinking of building a studio, and should esteem it a great favour if you could give me any advice on same. I am rather pushed for room. I have plenty of length, but only 10ft. in width, and thought of building one 24ft. x 10ft. What amount of glass would you advise? I am enclosing rough sketches. Which do you think the best construction suitable for a N.E. light? The studio would be rather overlooked. What glass would be most suitable?—**F. E. KINSEY.**

Opinions are very much divided as to which form is best—both are good. Personally, we should prefer No. 1. As the studio is so narrow 11ft. or 12ft. of glass will be ample. If the side is glazed with fluted glass no light will be obstructed, and it will not be overlooked. If you have space at your disposal we should advise that the studio be 3ft. or 4ft. longer; that would permit the use of lenses of longer foci than would be necessary were it only 24ft. long.

**ENLARGEMENTS ON CANVAS.**—Would you kindly answer, through columns of your paper, the following question? I am desirous of making club enlargements, 20 x 16, on wooden stretcher of calico or canvas. Could you give me a formula sensitising the cloth, as I understand that is the way they are done? Also some hints as to manipulating in development, etc.? Also where they can be bought commercially?—**NEMO.**

We much question if you will be able to prepare canvas for yourself at a price that would enable you to produce club portraits on it. If we mistake not, Messrs. Morgan and Kidd supply the canvas ready for use, and, if so, we should advise you to purchase it rather than attempt to prepare it for yourself on the small scale you would require it. Formula for working is supplied with the canvas.

**COPYRIGHT PROCEEDINGS.**—Will you please inform me how I am to get around publisher of picture postcards from a copyright photograph of mine taken in 1898? A postcard which I bought in a dealer's shop had on it name of "Hely, Printers, Dublin." Who am I to sue? I believe it was the dealer who sent the photograph. Could I sue if I had not the negative? What would be reasonable to sue for? It is of little or no use—negative at present torn. I had copyright in 1898. I have receipt from Stationers' Hall.—**PHIL CAHILL.**

You can sue the printers, the publishers, and the sellers of the piracies, or anyone who deals with them. The fact that you may not have the negative makes no difference. In suing, you will do well to sue for penalties, making damages a secondary consideration. The penalties awarded will probably come to a larger sum than any damages you can prove you have sustained by the sales. But you can sue for both. If you are a member of the Professional Photographers' Association we should advise

you to place the matter in its hands. It would save you a lot of trouble.

**BROBRINT.**—We are unable to account for your trouble, but I like to send us up the formula for your developer and unexposed cards we will try them and see if we can trace it.

**COMBINED BATH.**—Would you kindly give, in your "Answers to Correspondents," formula for combined toning and fixing bath, P.O.P., one which will keep well and give permanent print.

See the formulae in the "Almanac," p. 984. The permanency of the results depends on the care taken to avoid over-working the bath.

**EXPOSURE OF AUTOCHROME.**—I have carefully noted your instructions in the last issue of the "B.J." for the exposure of the Lumière plates, but I would thank you if you can give me an approximate idea of the differences of speed comparatively between Lumière plate and the Imperial S' S' 250 H. and D.—**J. M. A.**

The Autochrome with filter works out at about 2 to 3 H. and D. We give some further hints on exposure in the concluding part of this week's "Leader."

**COPYRIGHT.**—A goes to a sale and buys a quantity of negative original owner having recently died). B—at the same time amongst other articles he purchased—obtains the possession of the certificates of registration of a portion of the negatives by A. Has he any claim to stop A printing from the negative picture postcards?—**BURNLEY.**

Certainly not; but the sale of the negative without transfer of the copyright causes the latter to be destroyed—that is to say, anyone is at liberty to copy and print any of the photographs which you may take from the negatives.

**B. D. G. and others.**—In our next.

**W. BATES AND SONS.**—In our recent issues.

**H. H. THOMAS.**—Unless the copyrights are assigned to you at the time of purchase of the negatives, they become void, and anyone may copy the photographs. See the article in the "Almanac" for 1906, p. 652, where this and other questions are very fully explained.

**IMPROVER.**—We should say your best way would be to get an engagement with some good house as an improver at a salary, and then make the best of your time. With your present limited qualifications you must expect only very small results as you know but very little of the business.

**A. CAMBRIDGE.**—It is impossible to say what you should get, but you know nothing of your work or speed.

**CLASSES IN PHOTOGRAPHY.**—Mr. E. Senior, the well-known photographic expert, will conduct classes in all branches of photography at the Battersea Polytechnic on Tuesday and Thursday evenings, and at the Woolwich Polytechnic on Wednesday evenings. Programs, together with syllabus, etc., may be obtained on application to the above-mentioned institutions.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received for publication only on the understanding that they are subject to the approval of the Publishers, and advertisements are not published absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

### SUMMARY.

A text-book giving practical instruction in the use of Autochrome plates has been issued by Messrs. Houghtons, Ltd., at the moderate price of 2d.

"The Amateur Photographer" finds the Autochrome plate amenable to reasonable methods of after-treatment. (P. 772.)

The first accessory to the Autochrome process has emanated from the firm of Fallowfield. (P. 774.)

A practical note on the Autochrome process. (P. 762.)

The technical and lay press, with one exception, have reviewed the exhibition of the Society of Colour Photographers. (P. 766.)

The Warner-Powrie Process. We reproduce enlargements, of various diameters, of a portion of a Warner-Powrie screen-plate positive of the continuous-tone positive obtained from it. The two demonstrate the accuracy with which the linear ruling of the plate is eliminated. (P. 763.)

Mr. E. Grills contributes some practical notes on printing in pinatype from the Warner-Powrie negative. (P. 764.)

The patent specifications of Dr. J. H. Smith for bleach-out (Uto) never appear in this week's "Patent News." (P. 771.)

The R.P.S. Exhibition. Our concluding notice embraces the examples of professional portraiture and the trade exhibits, among which are several interesting novelties. (P. 767.)

We refer to the failure of the recent arrangements of the Royal Photographic Society in reference to the inclusion of professional photography in the annual exhibition. If professional portraiture was thought necessary to the annual display at the New Gallery, revision of the present regulations would appear to be necessary. (P. 762.)

### EX CATHEDRA.

#### Instruction in the Autochrome Process.

By the time these lines appear, a booklet on the use of the Autochrome plates will be obtainable throughout the United Kingdom, and will, there can be little

doubt, be eagerly read by those practising the new process. The manual is issued under the title "Colour-Photography with the Lumière Autochrome Plates," and is the joint work of Mr. George E. Brown, Editor of "The British Journal of Photography," and Mr. C. Welborne Piper. It is issued by and is obtainable in wholesale quantities only from Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C., and 70-78, York Street, Glasgow. Its price is but 2d., yet it deals without waste of words, and in the simplest language, with the practice of the Autochrome process. It should be particularly noted that the booklet is not obtainable from "The British Journal of Photography," except over the counter in single copies. All orders by post, and all inquiries as to copies for re-sale, should be addressed to Messrs. Houghtons. Neglect of the fact will only lead to delay in the supply of copies, for which there is already a very large demand.

\* \* \*

#### The Artificial Light Exhibition.

Our arrangements for the exhibition of examples of portraiture by artificial light by existing methods are now concluded, and we may therefore announce the date of November 1, on which the collection will be opened for inspection. The exhibits, it should be understood, are shown in every instance as specimens of the average work produced by the exhibitors, and therefore are retouched and otherwise prepared as customary in the establishments from which they emanate. That this will not in any way diminish the interest in the exhibition, but rather intensify it, is evident from a letter received from a well-known professional photographer, who, in so many words, writes: "I think the idea of the exhibition a fine one. It may not be scientific to show the comparative result plus retouching, but practically and commercially it's the only basis of comparison. If such and such work can be done by artificial light, that is all I, as a professional photographer, want to know." Admission to the exhibition, as to the present collection of colour photographs, will be free on signing a visitors' book.

\* \* \*

#### A Precaution in the Autochrome Process.

At one stage of the process of producing an Autochrome there is a possibility of mishap that is likely to be overlooked. It has been complained that the intensifying solution at times deposits silver in wrong parts of the plate, and thereby fogs the image. The reason of this is not likely to be the nature of the intensifying formula,

as has been suggested, but rather traces of the amidol developer, D, left in the film. Solution E is intended to destroy this developer, but if applied too soon it will fail to do so. If the developer is in excess it is Solution E that is destroyed, and if this happens it can be at once detected by the solution rapidly losing its pink colour and changing to brown. If the washing between D and E is sufficient the latter solution will still be pink at the end of the ten seconds for which it is applied. It is, therefore, important not to scamp the washing after the re-development, and it is best to wash for the full forty seconds prescribed.

\* \* \*

#### Securing White in Autochromes.

As we have pointed out, one of the effects of over-exposure of an Autochrome is a pink tint in the whites, or what should be the whites of the picture. If exposure is very much overdone, all the faint tints turn pink, and all distinction between them is lost. The whites and the light tones are then all of the same pink tint, which is very slightly deeper than the pink of the starch grain screen. There can be no doubt that the tint is that of the grain screen, deepened, perhaps, by a little fog in the upper film, and the question has often been asked, How is it that a perfect white can be obtained at all, considering that the screen itself is so distinctly coloured? One suggested explanation is that the white is only an effect of contrast. It is, however, a little difficult to see how the pink could possibly be changed to white as an effect of contrast alone, and experimentally we have failed to produce any such change. If the whites are slightly pink to start with, no amount of intensification will turn them to white, even though the contrast may be greatly increased. As we have pointed out above, under-exposure turns the whites blue and gives a bluish veil of fog over the rest of the colours. In this fact we believe the explanation of the production of white is to be found. If, owing to slight under-exposure, the colour of the pink screen is slightly veiled by a faint bluish or greenish complementary tint, then grey should be produced, and, if sufficient contrast is present, this grey should give the effect of white. From this it would appear that pure whites are only obtained when the plate is slightly under-exposed, and from our experience we believe this is actually the case. It may be asked, Why should not the exposure that gives white be called "correct"? We can, however, hardly consider exposure to be correct when the highest lights are veiled, and as a matter of fact in some subjects, especially those containing much green or yellow, traces of under-exposure are apparent when the

whites are good. It would appear that in the ideal the screen should be a perfectly neutral tint that would appear white by contrast, and until this ideal is attained we must make a certain amount of compromise in exposure to secure good whites.

\* \* \*

#### Control of Gradation.

In connection with the "Polytechnic" classes referred to on another page it is interesting to note that special attention is being given to the control of gradation. This is an old subject with Mr. Farmer, both as regards half-tone negative making and direct bromide enlarging, and many of our readers will remember the illustrated paper read before the Royal Photographic Society some three or half years ago, in which control of gradation in bromide enlarging was obtained by the aid of an ordinary half-tone Levy screen or a reproduction of such a screen. Apparently much time has been given to an exhaustive series of further experiments, and it is now capable of demonstrating that control can be obtained and the gradations vastly improved by instrumental means. We gather that the control of gradation is really the bringing of the steepness of the scale of the negative within the compass of the bromide paper without in any way modifying the negative by chemical or mechanical reduction, and if this can be done, the calculation being made from a formula, the production of harmonious results either in direct enlarging or enlarged negative making will be enormously simplified.

#### PROFESSIONAL PHOTOGRAPHERS AS PAYING GUESTS AT THE R.P.S. EXHIBITION.

A few years ago there was something in the nature of agitation on the part of professional photographers for greater amount of recognition of professional work by the Royal Photographic Society. The result was that at annual exhibition a room was set apart for such work, the wall space being rented to the exhibitors who hung whatever work they wished. Some exceedingly fine displays of professional work have been seen from year to year, and, presumably, those who have exhibited their work have done so, either in order to see it under similar conditions with the work of their confrères from other parts of the country, or in order to educate the public taste to what is good in portrait photography. It is difficult to see that the showing of work in a London gallery can be of much benefit to a professional whose studio is situated in, say, Penzance or Keswick, from any adverse

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### SCREEN-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1908 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

point of view. This year, if we accept the ordinary definition of a professional as a portrait photographer, the number of professional displays has dwindled to three. Mr. Hollier is, of course, well known as a professional, and his present exhibit, consisting as it does of platinum type reproductions, is brought rather more under the head of publication work than of regular professional photography. The interesting and beautiful prints composing Mr. Staengl's display are quite a trade exhibit which has doubt been crowded out of the North Room. This falling off in the number of workers will possibly mean an abandonment of the professional section as at present constituted another year. It is, indeed, doubtful if such section is what professional photographers really wanted when they asked for more consideration. Some years ago there was perhaps more tendency than can readily be believed to-day to show work which was characterised by softened definition, and many professionals regarded this diffusion as a defect, and could not understand the recognition of many of the examples as pictorial work. Their own clean-cut specimens of in many cases difficult subjects in portraiture, architecture, and other branches appealed to themselves. They were regarded, and rightly so, as *tours de force* and as examples of high technical skill, and the recognition which would have been appreciated would have been the institution of a separate class for professional work in which coveted awards would be given. The technical section of the R.P.S. exhibition of the present is rather to be regarded as a collection of scientific work in which commercial photography stands no chance at all of receiving any award. We are not merely expressing our own view in this matter, but are giving the opinions of a great many of our readers with whom we are brought into contact. This is not the place for time for discussing the matter from all points of view, but there is naturally much to be said both for and against. The awards were very limited a good deal of heart-burn would doubtless ensue, and to multiply the medals would be to cheapen both them and the society offering them, in the eyes of all the better workers. At the same time, the Royal Photographic Society is a catholic body which seeks to encourage all branches of the photographic art and trade, and the present exhibition unmistakably demonstrates the failure of a method which has been tried in connection with professional photography. We know we shall be told that the professional section

is open to any portrait photographer who likes to hire space in it, and the pictorial section is not necessarily closed to any professional electing to submit his work to the committee, merely because he is a professional. Both arguments, however, though perfectly sound, do not help in any way towards a representation of the good professional work at the Royal. For whatever we may think of, or hope for, professional photography, the fact remains that in the bulk it is commercial work, done for gain, and, therefore, done, in the great majority of cases, in a way which will commend itself to the photographers' patrons. There are photographers who can afford to say, "Take the portrait as I offer it to you, or seek another studio"; but the defiles of Bond Street are not exactly as thick with them as Vallombrosa with autumn leaves. And thus the professional's work is in this respect on a different footing from that of the amateur. We do not say it always will be, but at present it is, and the arrangements of the Royal Photographic Society in regard to professional work are, of course, a recognition of the fact. Yet they have failed to produce a sustained display of the best professional work for a reason which is not very far to seek. The Royal Photographic Society proposed to recognise professional photography by exhibiting examples at so much per square foot. In doing so they put all photographers on a level as regards the right to exhibit, although no indication of that equal monetary basis is given to the visitor to the exhibition, or to those into whose hands the catalogue falls. Is it surprising, then, that many of the very best photographers should be quite satisfied to be outside if their work is to be shown under conditions which can most easily mislead the public into supposing that their work is regarded by a great and unique body like the Royal Photographic Society, as on a level with that of anybody who can engage space for the display of their work? The remedy is for the Royal to abandon the "paying guest" system, and either by open competition or invitation procure, what is most easily procurable, a selection of works showing the best work in professional portraiture in this and other countries. It would be invidious to name those in this country who would strengthen such a scheme as this, but on the Continent, men like Dührkoop, Raupp, and Perscheid—we have seen this year how the Germans have progressed—could, and would, contribute work which would make the professional section at the Royal a source of strength to the Exhibition.

## SCREEN-PLATE COLOUR PHOTOGRAPHY BY THE WARNER-POWRIE PROCESS.

There can be no doubt that, in spite of the fact that they themselves are not yet on the market, very great interest has been shown in the Warner-Powrie process, and it has generally been conceded that the process possesses characteristics which should assure it a place among the one or two processes which are of practical usefulness. This is a small estimation of its future; but when the verdict of the majority, after practice of the process, is not forthcoming, just as well to let events speak for themselves. We may, however, reproduce here a couple of photographs which go to show the thoroughly practical character of the process. Both enlargements to eight diameters, the one (Fig. 1) of a Warner-Powrie colour positive representing a small portion— $\frac{1}{8}$  in. by  $\frac{1}{8}$  in.—of No. 84 of the transparencies in the exhibition of the Society of Colour Photographers. The other

(Fig. 2) is a similar enlargement of the continuous tone positive (the yellow printer) made from it, and a comparison of the two will show the very insignificant loss of structure occasioned by the triplicating of the image distributed through the colour-plate. The reproduction, which is the same size as the enlargement, represents a piece of a print enlarged on a scale which would give a print 24 in. square from a lantern slide. When the original from which the block was made is examined at the normal distance at which a print of such size would be viewed, namely, about 3 ft., the sharpness of the best-defined parts of the subject is more than enough for satisfactory definition; in other words, the pair of examples show the workable character of the process as regards making three-colour prints from enlargements of the continuous tone positives.

As regards paper prints from the Warner-Powrie negatives,

which have undergone this splitting process, there are now in the Exhibition of the Society of Colour Photographers several examples from the three positives, the method of obtaining which (the positives) has been described in our issue

thus formed of the correspondence of the details in the print with those in the original. In this connection we may print an article by Mr. E. Grills on the making of a set of positives and the printing therefrom in pinatype.

FIG. 1.

of September 13. These prints include a pinatype print made by Mr. E. Grills, and a three-colour carbon print on Rotary pigment films by Mr. Henry J. Comley. The negatives of both of these may be seen among the transparencies, and a judgment

can vouch for the authenticity of the negative from which Grills has worked, for it was taken by ourselves on one of the very few Warner-Powrie screen-plates available at present in this country.

#### PINATYPE PRINTS FROM THE WARNER-POWRIE SCREEN-PLATE NEGATIVE.

The introduction of the Warner-Powrie plate gives the pinatype worker a new power, as several of the stages are cut out altogether. This, on the face of it, does, and must, help one considerably in working pinatype, for it is on the quality of the diapositives that much depends, and by the use of the Warner-Powrie plate and three primary filters diapositive making becomes almost automatic. Another advantage of the Warner-Powrie plate for pinatype is that a transparent place, such as a cross, may be scratched in the film at either end of the plate, which will then appear on each diapositive and enable one to effect register of the colours easily.

The method of making the set of continuous-tone colour-sensation positives has already been described in these pages, so that I need not describe it further than to allude to my experience in working the process with the usual pinatype materials from a Warner-Powrie negative taken recently by the Editor of "The British Journal of Photography," and kindly placed at my disposal by Mr. Powrie. As has been mentioned, the angle of tilting must not be great. Four degrees is quite sufficient to cause the set of bands (in this case the red) to overlap to meet each other, and this is the reason why a thick glass should not be used, as an angle a little more acute than four degrees would have no detrimental effect when using the thin millimetre glass, but probably would, to some considerable extent, were the glass very much thicker, as the lines would then overlap from one series to the next. Of course, the angle of exposing is probably determined by the fineness

of the ruling, which at present is, I believe about 620 lines per inch, but in all probability, when Mr. Powrie introduces a new plate, as he anticipates, of even finer ruling, the glasses have to be still thinner, or maybe some other transparent substance, such as celluloid, will probably answer the purpose nearly as well.

The set of filters which I made for this process requires the same ratio of exposures for all three—red, green, and blue—respectively—using an ordinary 16 c.p. carbon filament lamp and a descent electric lamp. This is an advantage, as the first exposure determines the three.

For the making of the continuous-tone positives a chromatic plate must be used, but preferably one of the slow speed, as a fast negative plate, such as the Wratten & Wainwright chromatic, does not easily give the contrast which is needed for pinatype work. Moreover, such slow plates can be handled in a green light amply sufficient for convenient working. My own work was done in complete comfort by the aid of a candle-power lamp with a screen composed of one deeply blue film of naphthol green and one of fast green deep blue (Bayer) with a sheet of ground celluloid in between. The plates were not shielded from the light at any period, nor was there the slightest trace of fog. Dianol as the developer worked well.

There is a little to be said, too, on filters that are suitable for obtaining diapositives by this unique method. In the first place, they need not be at all expensive, as plate glass

ite unnecessary, as they have merely to be placed in front the printing frame when making the exposures; and for at matter they may be ordinary fixed-out dry plates suitably ined, and it is of this staining I wish to speak.

In the first place, it is to be quite understood that each set coloured lines on the Powrie negative (of which, of course, are three) has at the back of them a deposit of silver; record of the particular colour-sensation.

Assuming that we have the green, it is a fact that the absorption of the dyes on the Powrie plate are rather gradual—that they overlap rather considerably. Whether this is advisable or not does not for the moment matter, but it is certain that green lines transmit orange to some considerable extent. Hence it follows that were a red screen used to get a record

abled to get a clean sharp record of each coloured set of lines or bands without admixture of either of the other colours. What is true of the green is true of the others also, but when one remembers how easy it is by staining with suitable dyes to make a set of abrupt absorption filters, this is perhaps of little consequence. For instance, the red filter could be made of one plate stained with rhodamine or rose bengal with another of mandarin orange G. with a little picric acid. This would transmit the orange of the spectrum, but another film or plate stained lightly with brilliant green would absorb the undesirable orange and give a combination passing only the pure red.

Other dyes for the green and blue filters are just as easily made, although it is not my intention to dwell on them now,

Fig. 2.

the red lines, or, rather, of the silver underlying them, this filter or screen would transmit not only red but orange and yellow also (as do the majority of tricolour filters). Under these conditions not only would the red lines be recorded, but the green ones to some considerable extent also, so that it is obviously essential that filters for this purpose should have an abrupt cut or absorption, so that only light of the sensory colours of high purity be transmitted. One is thus en-

abled to get a clean sharp record of each coloured set of lines or bands without admixture of either of the other colours. What is true of the green is true of the others also, but when one remembers how easy it is by staining with suitable dyes to make a set of abrupt absorption filters, this is perhaps of little consequence. For instance, the red filter could be made of one plate stained with rhodamine or rose bengal with another of mandarin orange G. with a little picric acid. This would transmit the orange of the spectrum, but another film or plate stained lightly with brilliant green would absorb the undesirable orange and give a combination passing only the pure red.

E. GRILLS.

**PHOTOGRAPHIC INSTRUCTION AT THE POLYTECHNIC.**—Next Tuesday, October 15, is the opening night of the classes of the Photographic School at the Regent Street Polytechnic. On that evening at eight o'clock, in the large hall of the "Poly," Mr. E. B. Knobel, R.A.S., the managing director of Ilford Limited, will preside over a meeting of past, present, and intending students of the school, before whom Mr. Howard Farmer, Principal of the school, will give an address, the nature of which is foreshadowed by particulars published in the prospectus of the school. From these we learn that by means of a so-called "Ratiometer Lens," to be supplied by Messrs. John J. Griffin and Sons, it will be possible to control the gradation values of a negative in making portrait and other negatives. We learn that the use of this instrument is to be the subject of an instruction course at the Polytechnic. In addition, the announcements will be made as to the facilities now available

for "Poly" students qualifying as press photographers, and as to new methods in three-colour and half-tone block making. These promises, which we know Mr. Farmer would not make if he were not prepared to substantiate them, ought to be sufficient to draw an interested audience to Regent Street on Tuesday, when Mr. Farmer, as a photographic Duke of Plaza Toro, will produce "examples illustrative." Of the photographic classes at the Polytechnic it is only necessary for us to refer the reader to the full prospectus and to the names of the teaching staff, among which in addition to that of the Principal will be found Mr. C. H. Hewitt, F.R.P.S., Mr. Wolfgang Arndt, Mr. A. J. Lyddon, and Mr. G. C. Laws, in whose charge are the courses of instruction in posing and lighting, negative making and printing, retouching, and working up, and in the various sub-branches of photographic practice.

## THE SOCIETY OF COLOUR PHOTOGRAPHERS.

THE fact that—during the seven complete days which, at the time of writing, the exhibition of the Society of Colour Photographers has been open—over 1,000 persons have inspected the collection at the house of “The British Journal of Photography” is some indication of the interest which the new colour processes have aroused. And it is evident, too, that this interest is not confined to those who had already practised ordinary photography, or were even ordinarily familiar with its processes. It is clear that the fascination of colour will induce many people who have never touched a camera to purchase and use one solely with the object of securing results in the colours of nature, and it may not be long before we have text-books written only for the instruction of those who know as little of P.O.P. as they do of the binomial theorem, yet have come under the spell of camera work with the screen-plate methods. To what extent this will be remains to be seen, but there are, we find, signs of it.

As regards the present exhibition, there are one or two items which we are requested to announce in respect to examples which have been added to the exhibition since the catalogue went to press. Among these are several further Autochromes from Dr. Grundlach, of the staff of Carl Zeiss. These include a remarkable portrait of Professor Ernst Haeckel, the eminent biologist, taken at his home in Jena. There are also several landscapes of scenery in the Tyrol and near Jena, which are separately indicated.

An Autochrome of a garden scene by Mr. Max Poser, of the London house of Carl Zeiss.

### THE TECHNICAL AND DAILY PRESS ON THE EXHIBITION.

“The Times” says:—“With the exception of the remarkable three-colour prints by Mr. H. J. Comley, there is little which indicates any distinct progress. But the transparent positives, shown under conditions of lighting which reflect credit on the organisers of the exhibition, will surprise the uninitiated. These transparencies are made by the autochrome or starch-grain process, by Mr. Sanger-Shepherd’s trichromatic method, or by the Warner-Powrie process, which, unlike the Lumière process, readily admits of the duplication of the colour prints on glass, by a process similar to that by which the plate is made in the first instance, and on paper by the existing three-colour methods.”

The “Daily Graphic” considers that “the exhibition affords an interesting opportunity for students to compare the results achieved by different processes. Mr. Henry J. Comley, of Stroud, Gloucester, has some particularly successful prints. His ‘Primroses’ is as nearly as possible the real thing, and with it deserves to be mentioned the ‘Evening from the Pic du Midi’ of E. D. Doncaster. The ‘German Vase,’ of Mr. Harold Hood, challenges comparison with the original standing in the room, and comes out of the test very well.”

The “Westminster Gazette” writes:—“The Sanger-Shepherd process is also well represented in the room, and so are several very similar three-plate processes by well-known experts. In comparing the old with the new processes, visitors should understand that the autochromes all represent a new and unfamiliar process, and that many of them are by workers who had never attempted colour-work until the last few weeks, when the plates first became obtainable. The true colour rendering obtained in many of the examples is, in these circumstances, sufficient proof of the ease with which the process is carried out.”

Mr. Horsley Hinton, describing the exhibition in the “Daily Telegraph” as “thoroughly representative of colour-photography,” accords “the first place to the works of Mr. Henry J. Comley, the honorary secretary of the Society of Colour Photographers, and the gentleman to whose initiative we largely owe the formation of that society; and the recognition of his premier position is due simply on the ground of the merit of his work. Mr. Comley was known as one of the most successful photographers in natural colours long

An excellent Autochrome portrait by Miss Acland, F.R.P. which, though catalogued, had been overlooked in arranging the transparencies, is now in place, and should be mentioned as a good example of restraint in applying the process. Miss Acland’s long practice in colour photography the Sanger-Shepherd process has kept her from the common mistake of indulging the appetite for colour to excess. The portrait (No. 131) may well serve as a model of what should be attempted in a portrait of a lady by the process.

We should also refer to two prints by an Australian member of the Society of Colour Photographers, Mr. G. Ooneto, Perth, Western Australia, which are very fair examples of pinatype printing from negatives obtained with Wratten and Wright’s panchromatic plates and filters.

Dr. J. H. Smith, of Zurich, has also sent two large examples of the “Uto” bleach-out process, in the shape of copies from a colour lithophane transparency.

The interest taken in the Warner-Powrie process will be accentuated by the exhibition of four prints on paper prepared from negatives on the Warner-Powrie screen-plate. In two instances the negative is shown among the transparencies (Nos. 78 and 86), and the examples show the result of printing from the continuous tone positives by the pinatype and carbon three-colour processes, that by the latter being by Mr. Henry J. Comley, who shows the three constituent impressions forming the finished print.

The vase, which is the original of No. 49, by Mr. Harold Hood, may now be seen and compared with the reproduction to the credit of the latter.

before the society was established, and since its inception I devoted myself with redoubled energy to the work he loves. So will be recognised that Mr. Comley owes his success to persistent hard work and untiring devotion, certainly not to any formula or process, for he photographs in colours by all the various methods which are known.”

The “Amateur Photographer” writes:—“A feature of the exhibition is portraiture in the studio by the three-plate method, and would seem as if we are on the point of experiencing the regular use of heliochromy by the professional portraitist. Mr. Comley’s portrait of an officer in uniform (No. 12) may be mentioned, with the flesh tints in Mr. John Moffat’s ‘Japanese Girl’ (No. 17) wonderfully rendered, and in this connection we must not forget the portrait-work comprised in the collection of transparencies the Sanger-Shepherd process. As degrees of perfection in colour rendering are very inadequately indicated by effusive language, I do not think it desirable to extend our notice, but we urge our readers to go and see how notable is the progress, and to judge for themselves whether we are not actually on the threshold of a period in which colour photography will be an every-day occupation for the amateur.”

Our contemporary “Photography,” which has recently informed its readers of its proposition to deal “with all matters of interest to the amateur colour worker,” says:—

“Focus” writes:—“The section devoted to transparencies includes examples in the new Warner-Powrie and Lumière processes, and the well-known Sanger-Shepherd method. To our mind the light behind these transparencies is much too powerful; not only is it injurious to the plates, but it is trying to the eyes. Both the Warner-Powrie

the Autochrome plates here show a pervading pinkiness which does not commend itself. The Sanger-Shepherd transparencies certainly hold their own in this display. Comparing the Warner-Powrie's and the Autochromes, we find little to choose between the two. The transparencies of continuous tone positives from the Warner-Powrie plate is an interesting exhibit showing how it is possible to produce from this plate a positive of the same character as that obtained from an ordinary negative." "M. B.," in the "Pall Mall Gazette," says:—"The work of the secretary, Mr. Henry J. Comley, is far superior in quality and value to that of any other exhibitor. Nearly all his pictures are fine indeed, and it was only their high quality that prevented them from forming the conclusion that colour photography on paper is practically impossible for the amateur worker. Mr. Comley shows

that it is possible. He cannot, I fear, show us that it is easy and inexpensive. And it is instructive to note that the best results are obtained throughout from portraits and 'still life' subjects taken indoors. I do not recollect seeing a single really satisfactory print of a landscape subject, taken direct from nature, in the whole collection. But I do not wish in any way to condemn the section as useless because the majority of the results fall far short of perfection. It has been said, with no little truth, that research which fails may be almost as useful as that which succeeds, and I feel sure that those who have 'been through the mill' of complicated colour work will have acquired a knowledge of colour and its relation to photography, which cannot fail to be of service to them in their subsequent experiments with simpler processes yet to be discovered."

## THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

In concluding the notice of the Royal Photographic Society's exhibition which commenced in our issue of September 27, we review what samples of professional work are to be seen at the New Gallery. Our regret and that of a good many more that the representation of professional photography should be so slender. Without the magnificent work of Mr. Crooke it would make a sorry show indeed, yet the cause seems plain enough and the remedy simple enough.

### THE PROFESSIONAL SECTION.

Regarding the general character of this section and its future we make some suggestions to offer in the Editorial on another page. It is to be regrettable for the section to disappear, as it almost does at the present occasion, from the exhibition.

There are, however, a number of pictures in the section this year which many of our professional readers who are up in town will say the shows may learn valuable lessons. The Canadian studio, for example, shows one or two good child studies, and some ladies' portraits, in which both excellent modelling and fine drapery textures may be seen. The two large portraits of men lack strength, partly used they are rather over-retouched, and also doubtless because of the figure, as well as the head, is quite a side view. The top print somewhat heavy flesh tones, and too strong a high-light on the forehead.

The Mattype Company's display shows remarkably even quality technique. The negatives are evidently well lighted, properly exposed, and evenly retouched; but there is a rather monotonous effect about the results which forces on one the conclusion that the portraits cannot show much of the sitter's individuality. The vignettes in several cases strikes one as being rather too close; a nose ends to disappear and a neck and shoulders seem inadequate to support a head. The plain warm tinted oak in which the pictures are set is in good taste and quietly effective.

One may be learned in the matter of copying from a study of Hollyer's fine reproductions. The portraits of Charlotte Brontë and George Eliot convey a very good idea of what the originals must have been like in light and dark chalk on a toned paper. Contrast the two prints of Mrs. Siddons with the portrait of Mrs. Fry, and W. B. Richmond, and note how the character of the negative is according to the feeling of the original work. The framing of these platinotype reproductions is very effective. Plain wood cases, with merely a narrow gilt hollow near the outer edge, are added to a warm, almost dull, brown.

Not only does the wall occupied by the work of Mr. William Crooke contain some of the best work in the room, but it holds some of the finest prints in the whole exhibition. In No. 2, a "Portrait of John de Burgh," on a cream-toned paper, we have the soft definition

for the Royal to consider a revision of its arrangements another year. We dismiss, and we believe the Royal will dismiss, the financial side of the question altogether, and therefore we offer, on another page, a few notes which we trust will be perused by professional photographers themselves, as well as by the Exhibition Committee of the society.

The Trade Section this year, as will be seen from the notes which follow, contains several items of great interest.

and tones which one associates with a fine pastel portrait. This quality of definition should be carefully studied, as the average professional enlarged portrait tends to harshness of outline, particularly when the original negative has good printing strength and if a side light has been used. The rich quality of the shadows in No. 8 is worth attention, and No. 4 should be noticed on account of the strong dignified effect and the clever handling of accessories and uniform in the management of the composition. No. 3, "A Portrait of Sister Margaret," is very fine, far removed from the ordinary "pretty" type of portrait. There is genuine sweetness and much strength. The sitter has a good deal of strong character, and this is retained and well expressed in the portrait, which is a work that one might hang on one's wall and have pleasure in contemplating. The natural yet quiet arrangement in "Portrait of a Mother and Child" is worth noting. This has fine quality in the background, which, though it occupies a large proportion of the picture, does not appear either empty, on the one hand, or distracting on the other. "In Silk Attire" is one of the most charming portraits we have seen for a long time. The rendering of the dress is superb, and the portrait gives the impression of a dignified and gracious woman. The position of the highest light should be noticed, on the sleeve, and though the face is in shadow neither this light nor that on the dress is at all "jumpy." The delightful portrait of a child, neither grave nor gay, strikes one as being just what a child's portrait should be.

If we have left mention of the large group of the Edinburgh Town Council to the last it is by no means because we regard it as the least of Mr. Crooke's exhibits. We do not think the statement is likely to be controverted that this is the finest thing of its kind ever done by anyone. A close inspection of the picture, which is of large size, does not enable anyone to determine whether the portraits have been taken separately in the studio and painted into the picture of the interior of the Council Room, or whether the group has been taken in the room at one exposure. Every portrait is quite evidently a likeness, and we think it most likely that the picture is a magnificent specimen of combination printing; but in this case the management of the perspective, as regards the size of the figures according to their distance, has been arranged with consummate skill.

### TRADE EXHIBITS AT THE R.P.S.

The Fountain Court of the New Gallery is occupied by the stalls of the trades, many of whom we have been accustomed to see in their places for years past. Messrs. Wellington and Ward on the left of the entrance make an even more artistic display of their wares than they have done in previous years. On this occasion,

as may be expected, the facilities of the "Watalu" self-developing plate are a prominent feature, and visitors to the miniature salon will be able to learn particulars of a new "Watalu" plate intended for lantern and transparency work. All the Wellington products, including the well-known lines of bromide, printing-out, and self-

toning papers get a very good showing indeed under the stage management of Mr. George Walton, and no one, we imagine, will find any fault with the personal representation of the firm by Mr. A. C. Baldwin.

On the other side of the doorway the Kodak Company exhibit among many other of their later introductions a new quarter-plate reflex camera which they are issuing at the popular price of two guineas, and which in its way is a triumph of simplicity in hand camera manipulation. We may reasonably claim to know what there is to be known of reflex cameras upon the market, yet we can say that in carrying out what it claims to do the new "Premograph," as it is called, is approached by no other instrument. The camera is not a focussing instrument, but it permits of the viewing of the image on the focussing screen in full size up to the moment of exposure. The combination of shutter and mirror is most ingenious, and it is one of the exhibits at the Royal which ought to be seen. Later varieties of the Kodak daylight developing tank also attract attention at this stall, where also are exhibited specimens of dry mounting materials now being supplied by the Kodak firm.

Resuming the tour of Fountain Court we find Messrs. J. H. Dallmeyer, Ltd., offering a small though quite interesting exhibit of work with their "Adon" lens, and of specimens of the "Adon" and "Junior Adon" instruments themselves. The slim "Packard" shutters, introduced last year, may also again be seen.

#### Colour Processes—Sanger-Shepherd.

The sudden accession of interest in all matters connected with colour photography is no doubt responsible for the fact that Messrs. Sanger-Shepherd's stall attracts a more persistent and interested crowd of visitors than any other in the exhibition. Their arrangements allow Messrs. Sanger-Shepherd to show the facilities and qualities of their process in a most convincing way. Visitors can see here for themselves the brilliancy and perfection of the Sanger-Shepherd colour process for transparencies, whilst they can make themselves acquainted with the apparatus, of which this firm alone has long made a special study. Among others we see signalled a new attachment for the studio camera allowing of very rapid exchange of the three plates, each with its filter. The movement is sufficiently easy and automatic to allow for a second or two sufficing for all three exposures, and the new back should be of interest to those contemplating this very practical method of three-colour work in conjunction with a newly introduced set of filters which, being somewhat less "strong," permit of shorter exposures being given to the plates. Landscape and amateur workers in colour photography should also make a note of the Sanger-Shepherd prism one-exposure camera, an instrument so unassuming externally that it might be mistaken for an ordinary guinea magazine camera. Its internal construction, however, dispensing entirely with mirrors, and obtaining the three-colour sensation negatives on one plate by means of a very finely adjusted arrangement of prisms, makes it possible for the three-colour negatives to be obtained at one exposure in a time which in bright light in the southern latitudes may permit of the worker using the camera in the hand. The instrument is made in two sizes, the smaller using a plate, half-plate, and giving the three pictures about two inches square, whilst the other takes a plate  $8 \times \frac{3}{4}$ , and gives a picture of somewhat larger dimensions. In the domain of orthochromatic photography the graduated wedge colour screen of the Sanger-Shepherd firm is to be seen together with some very fine examples of its use in landscape work by Mr. H. G. Ponting. There would seem a likelihood that still more will be heard of the graduated colour filter in conjunction with the new Lumière plates, the rendering of the sky in which is one of the points of the process which appears to offer some difficulty, and no doubt Messrs. Sanger-Shepherd, from their special facilities in providing colour screens of all kinds will be able to provide a means of effecting the necessary local control on the plate. Of filter attachments for hand and stand cameras the convenient slide-past holder carrying a set of three yellow screens of different depths or a set of three three-colour filters are particularly worth attention, and the very neat and portable way in which they may be fitted to such standard hand cameras as "Videx," etc., should merit the notice of the more serious worker as permitting him to provide himself for colour work without greatly augmenting his outfit. The amateur colour worker who wishes to control his methods by ordinary simple means may also be referred to the

prism spectroscope made by Messrs. Sanger-Shepherd at the price of a guinea, and of considerable service in examining light filters, testing the dark-room light, etc.

Still one other exhibit calls for notice, namely, the Sanger-Shepherd photographic survey camera, which, while generally of the lines of these instruments, is an improvement on them in several important particulars, and is deserving of the attention of those interested in this application of photography.

#### Messrs. O. Sichel and Co., C. P. Goerz and Co., W. Watson and Sons.

Messrs. Sichel exhibit a large selection of their many specialities, notable among which is the mercury vapour printing and portraiture apparatus already reviewed in our columns. Other accessories of interest to the professional photographer are found in the "Edward" and "Sickle" studio cameras, the "Sickle" studio shutters, and backgrounds in several varieties, and specimens of trimming and cutting machines, and of the "Ingento" and "Idem" embossing presses. Appealing primarily to the professional photographer, Messrs. Sichel's exhibit should certainly be closely examined by our readers.

The house of C. P. Goerz exhibits a number of very striking enlargements from negatives taken from the Goerz lenses. These instruments themselves are worthy of inspection even by the casual visitor, who can see for himself the beautiful mechanical work which characterises the Goerz lenses and shutters. The photographic enlarger should convince him of their optical qualities. A new introduction is the "Tenax" camera, a highly portable and efficient hand camera which we hope to review at greater length very shortly.

The great interest taken by the professional photographer in systems of artificial lighting is one to which Messrs. W. Watson and Sons show that they are fully alive by the prominence given at their stall to the Boardman arc lamp for studio portraiture, and to the "Acme" flashlight apparatus. They show also a number of examples of their own manufactures in cameras and accessories, and of the well known series of "Holistigmat" actinolux lenses. We should not omit also to refer readers to the series of "Argus" reflex cameras, which we know have met with wide appreciation in the press and serious hand camera work.

#### "Tabloid" and "Birdland."

Messrs. Burroughs, Welcome and Co. make their usual interesting and unpretending exhibit of tabloid chemicals, and demonstrate intervals the newly introduced chromium intensifier of Mr. W. B. Piper and other "tabloid" reagents.

At the adjoining stall of Messrs. Sanders and Crowhurst the latest models of the "Birdland" camera, the "Birdland" tilting board, and the most efficient Southport enlarging easels and tables are to be seen. Some examples of the recent bird photography by Mr. Oliver G. Pike and Mr. H. Armytage Sanders should also be noticed.

#### Screen-Plate Colour Processes.

Messrs. Wratten and Wainwright, who within the last year or two have come to the front in the matters of plates and filters for colour photography have a striking exhibit in the shape of an illuminated stall showing the quality of the safe-lights and the colour and compensating filters issued by their firm. They also exhibit a complete series of examples showing the stages in the preparation of a cemented filter from the dye and gelatine to the finished screen, but the chief interest will no doubt centre upon a microscopic exhibit showing the actual screen-plates now so much to the fore as solving the problem of a simple and expeditious means of colour photography. Messrs. Wratten allow the visitor to see for himself through the microscope the Joly "taking" and "viewing" screens, the Lumière starch grain, and the Warner-Powrie line screen in addition to two other line and mosaic screens of German origin. Their exhibit enables the visitor to observe the relative mechanical perfection of these competitors for favour in screen-plate colour photography, whilst it suggests at the same time the activity which is quietly being shown by those intent upon supplying the amateur worker with these new materials.

#### The Twin Cooke Lens and a New Reflex.

Messrs. Taylor, Taylor, and Hobson have an exhibit which is of great interest to the professional worker—namely, a new variety of their well-known "Cooke" lenses in which in the one instrument of eight inches focus two fully corrected anastigmats of 14 and

focus respectively are provided. The first merit of the new lies in the convenient way in which the optical adjustment of the means of securing these variations in focal length is performed. The standard flange of the Cooke factory is, of course, responsible for the convenience which the lenses possess in respect, but there are two other points which to the profes-

COOKE PORTRAIT LENS.  
SERIES VI.  
T.T. & M.L.

sional worker especially are of importance. In the first place, by having a greater or less separation to one component of the lens a certain amount of diffusion of definition may be introduced into the negative. Such a device is not, of course, a novelty in lens construction, but the point in regard to which Messrs. Taylor, Taylor, and Hobson may reasonably claim commendation is that the adjustment has been so provided with a graduated scale that the photographer may repeat the production of diffusion of certain degree as much as he likes merely by setting the pointer attached to the lens at the same place on the scale each time. Further than this there is a flexible attachment from the front to the back of the camera, both diaphragm and diffusion scale, so that the effects of both are controllable while the eyes of the operator are fixed upon the viewing screen. The new lens is certainly one of the notable introductions of the year, and the demonstration which Messrs. Taylor, Taylor, and Hobson's representative gives should be one of the inducements for the professional photographer to visit the Newbery.

To the amateur worker the new reflex camera, first shown at the exhibition of these instruments at the house of the BRITISH JOURNAL OF PHOTOGRAPHY, may be seen. Since its first introduction Messrs. Taylor, Taylor, and Hobson have further improved it, particularly as regards the stereoscopic hood, and in one or two minor respects connected with the working of the shutter. As we have already noted, it is a reflex camera built the landscape way of the type and provided with a finder when making vertical pictures which nevertheless shows the alteration of the subject on the plate as the front of the camera is raised. The extraordinarily small dimensions of the instrument for a reflex camera will attract the tourist, who could be fully satisfied with the thorough mechanical workmanship which Messrs. Taylor, Taylor, and Hobson have given to their maiden effort in camera manufacture. It is sufficient for us to say that the reflex is quite on a level with the mechanical perfection of "Cooke" lenses, and probably no higher praise could be bestowed upon the new instrument than this.

#### Platinotype and Gaslight Printing.

The stall of the Platinotype Co. is an object lesson as regards lighting and decoration, and on that account, if on no other, is deserving of study from the professional portraitist who would learn something as to giving a more impressive effect to his own premises. The demonstrations, however, of the Platinotype Co.'s new "Japine" paper, which take place daily at 4.30 and 7.30, should attract a good many, for "Japine," by its rich and lustrous quality, may be said to have had wide favour already bestowed upon it and it differs sufficiently as regards manipulation from previous productions of the Platinotype Co. to repay anyone interested in the paper for a visit to an actual demonstration.

Among the wall displays of the photographic trade, attention first centres on that of Ilford, Ltd., in the North Room, where is brought

together a magnificent collection of prints and enlargements on the Ilford gaslight papers. The variety in tone and surface of these photographs is remarkable, the results on the portrait carbon surface being especially worthy of attention. The catalogue will tell the visitor how the warmer tones have been produced, and the exhibit is thus one of the most educative of those provided by the great photographic houses.

#### Diffusion in Portraiture.

Adjoining the Ilford screen is the display of Mr. F. C. Clarkson, who shows examples of the work of the Hermagis "Eidiscopes" lens permitting of any desired degree of softness in portraiture and landscape work, but nevertheless, as shown by several examples, allowing of the most exacting sharpness being produced should such be necessary.

#### Negative and Positive Processes.

The examples of Ozobrome, Ltd., show what can be done with this attractive form of carbon printing; one or two of the results by Messrs. Ellis and Walery are interesting as indicating the use made of ozobrome in commercial carbon enlargement making.

Of Messrs. B. J. Edwards and Co.'s exhibit it is sufficient to say that it includes a number of fine examples of isochromatism in landscape, in addition to other thoroughly good technical work on the Edwards plates, among the users of which represented are Mr. Martin Duncan and Mr. Horsley Hinton.

A striking exhibit is that of the Leto Photo Materials Co., whose specimen prints of the well-known "Seltona" and "Tintona" papers strike us as specially meritorious, although as regards effective display a greater reserve in hanging and more care in classifying the prints would benefit the exhibit as a whole.

The Autotype Co. show a number of their excellent reproductions of paintings in carbon and Auto-Gravure illustrating the satisfying results which those processes will give in reproducing the work of ancient and modern masters.

A similar exhibit of special interest to the professional worker is that of the enamels on copper and coloured miniatures on ivory, a line of work which the Autotype Co. have lately taken up with increased activity.

Two other exhibits in the North Room must be mentioned—namely that of George Smith, of the Sciopticon Co., which includes two frames of lantern slides of the highest technical quality produced by the Woodburytype process, and of L. Gaumont and Co., who show a most striking series of enlargements from negatives taken in the tiny "Blocknote" camera.

#### CATALOGUES AND TRADE NOTICES.

MESSRS. HARRINGTON BROTHERS' current list of fine chemicals reaches us for the current month, and is obtainable on applying to the firm at 4, Oliver's Yard, 53, City Road, E.C.

BARNET DEVELOPMENT PAPERS.—Under the title, "The Simple Art of Picture-making," Messrs. Elliott and Sons, Limited, have issued a 30-page booklet dealing with the manipulation of their bromide and gaslight papers, among which, as our readers should know, are such fine papers as "Lustra-matt," "Tiger-tongue," and "Oyster-shell." These descriptive titles do not belie the valuable qualities of the papers, and the booklet, dealing as it does with points in the manipulation of special application in the treatment of the papers, should be deserving of a careful study. It is illustrated with several useful reproductions, showing the effects to be aimed at—and avoided. Messrs. Elliott, Barnet, Herts, will send it free.

EXHIBITION AT WHITECHAPEL.—An exhibition illustrating "Animals in Art" will be open at the Whitechapel Art Gallery during October and November, admission free. Lectures relative to the subject of the exhibition will be given on certain evenings at 8 p.m., that on November 1, entitled "Art among Animals," being by the well known natural history lecturer, Mr. F. Martin Duncan, F.R.P.S. The Art Gallery is in High Street, Whitechapel, close to Aldgate Station, and should be well worth a visit from all lovers of natural history, to whom also the lectures—a list of which may be obtained on application to the secretary—should prove of special interest.

SOME GEMS OF THE PHOTOGRAPHIC SALON AS THEY APPEAR TO AN ARTIST IN BLACK-AND-WHITE

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for Patents have been received between September 23 and 28:—

**ARTIFICIAL LIGHT APPARATUS.**—No. 21,209. Improved apparatus for the production of photographic prints by the use of artificial light. Frederick Wilfrid Scott Stokes and Charles Jennings Hillman, 149, Strand, London.

**CAMERAS.**—No. 21,387. Improvements in folding cameras. Arthur Lewis Adams and Walter George Roberts, 24, Charing Cross Road, London.

**WHIRLING MACHINES.**—No. 21,388. Improvements in whirling or centrifugal machines. Arthur Lewis Adams, 24, Charing Cross Road, London.

**GRIPPING DEVICE.**—No. 21,432. Automatic adjustable gripping device for supporting various appliances in front of photographic or other lenses of varying diameters. Walter Tylar, 41, High Street, Aston, Birmingham.

**POSING DEVICE.**—No. 21,470. Photographic posing device. Frederick William Charles Pohle and Paul Werner, 18, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**BLEACH-OUT COLOUR PROCESS.**—No. 2,461, 1907. The invention consists in the following process of preparing bleach-out direct printing colour paper. The patentees write:—In the course of experiments for the production of bleachout sensitive surfaces we found that a regularity exists in regard to the wandering of dyes from a coating of one medium into that of another, more especially from gelatine into collodion (i.e. the nitrocellulose residue), and from this again into gelatine. The law rests on the strong tendency which acid dyes exhibit towards gelatine, whereas basic dyes possess a strong affinity towards nitro-cellulose. By acid dyes such dye stuffs are understood as contain an acid group, the residue of such a group or the ester of such a group. If a mixture of dyes in gelatine solution consisting of erythrosine, auramine, and methylene blue is coated upon a collodion base, the basic colours auramine and methylene blue wander into the collodion film and the resulting papers on examination show a green collodion film underneath a red gelatine film. If a mixture of the same dyes in collodion is coated upon a gelatine base, the erythrosine wanders into the gelatine, leaving a green collodion film upon a red gelatine film. If, instead of these colours, flavaniline (basic and flavaniline S) (acid) be employed, the former gives the same result as auramine, whereas flavaniline S wanders into the gelatine as erythrosine did. A mixture of flavaniline S, erythrosine and methylene blue in collodion coated upon a gelatine base yields an orange-coloured gelatine film upon a blue collodion film; if however in place of methylene blue an acid blue dye, e.g., naphthol blue 2 B be coated in collodion upon gelatine, a coloured gelatine film underneath a colourless collodion film is the result, or if coated in gelatine solution upon a collodion base a colourless collodion film underneath a coloured gelatine film is the result, in the latter case the dyes being already in a state of rest do not wander. If instead of three acid dyes three basic ones, e.g., safranine, auramine, and methylene blue, are employed in whichever medium they are mixed and coated coloured collodion and colourless gelatine are the result. If the basic dyes are coated in a gelatine solution upon a gelatine base underneath which is a collodion film, the basic dyes will wander through the gelatine base even should this be coloured with one or more acid dyes into the collodion film: the acid dyes behave similarly inasmuch as they will wander through a collodion layer to find their state of rest in a gelatine film.

In the preparation of bleach-out paper it was found advantageous in some cases to employ a mixture of both acid and basic dyes. It is not, however, possible to coat an emulsion containing both acid and basic dyes upon a paper support without a separation occurring. The separation was not only unavoidable but

necessary, because otherwise a reaction between the acid and basic dyes would have occurred.

It is exceeding difficult to coat with ordinary coating machinery a solution containing one or more dyes, as the slightest difference in the thickness of coating which would not be observed in the case of silver bromide paper or plates will form streaks which must be altogether avoided in the bleach-out process. To coat several layers of differently coloured dye solutions one upon another so that an evenly coloured harmonious surface results is almost impossible, the faults are increased in each successive coating so that one or other of the colours is in preponderance. This difficulty of coating a second film of colour emulsion may however be entirely overcome by the utilisation of the principle of wandering, inasmuch as the acid or basic dyes are given the opportunity to wander into a state of rest. The second coating can thus be dispensed with, as the separation of the dyes takes place automatically. The wandering is so regular that it is not possible to know from an inspection of the surface of the paper if it contains one or two coloured films, it being perfectly harmonious.

Other technical advantages pertaining in the application of the wandering principle may be mentioned. In cases where it is necessary to obtain absolutely sharp pictures it is necessary to have all the dyes contained in one layer; this might of course be obtained by the use of a coating of resin or lack, but this again would be accompanied by other technical difficulties, such as stickiness, slow drying, etc. It is much preferable to apply the principle mentioned above of the affinity shown by the dyes to certain layers of rest, and either coat the dyes in such a layer upon paper which has received a coating having no affinity to the dyes employed or to coat them in a layer having no affinity upon paper prepared with a coating for which the dyes have affinity, thus allowing them to wander to their position of rest. In the case of the employment of dyes in gelatine solution the emulsion may be coated direct upon collodion paper, whereas in the case of a mixture of basic dyes coated in gelatine solution upon collodion another gelatine coating would be required between the paper and the collodion film to prevent the dyes entering the tissue of the paper. In the case of coating acid dyes in collodion solution upon gelatine paper no such isolating layer is required, as the dyes have a greater affinity to the gelatine than to the paper; in the employment of basic dyes in collodion solution the emulsion may also be coated direct upon gelatine paper, as the dyes are already in their position of rest.

We have already referred to the process of obtaining two layers of differently coloured film; it is easy to see that by this means mixtures of basic and acid dyes can be separated at will in the simplest manner, so that the dyes may be brought or allowed to wander in the upper or lower stratum as may be most suitable for their being sensitised; the sensitisers being either added direct to the emulsion layer or allowed to be absorbed by the dyes from a sensitising bath into which the dyed films are subsequently placed, by which means the sensitiveness of the one layer may be increased by that of the other one. Instead of gelatine as matrix, other similar bodies—e.g., glue, isinglass, gum, albumen, casein, etc., may be employed, and instead of nitro-cellulose other cellulose derivatives—e.g., cellulose acetate, etc., may be used.

The following is a specific example of the production of a bleach-out film according to the present invention:—

Alcoholic solutions of erythrosine, auramine, and methylene blue are made and these added to a 3 per cent. collodion in such proportion that when a drop of the mixture is placed upon a glass plate or a piece of paper with a gelatine surface it dries to a neutral grey colour. An alcoholic solution of anethol or other suitable sensitiser or of mixtures of such is then added to the emulsion and the emulsion coated upon paper which has received a preliminary coating of gelatine. The coating of the paper may be done upon an ordinary paper coating machine, but it was found preferable to coat the dyed collodion emulsion upon a plate coating machine, the gelatinised paper having been first cut in sheets and mounted on sheets of plate glass.

When dry the paper sheets were cut round the edges and

stripped from their glass support. The erythrosin had wandered into the gelatine layer while the two basic dyes remained in the collodion layer.

The resulting paper requires sensitising with peroxyde of hydrogen, as the erythrosin is isolated from the sensitisers contained in the emulsion.

If instead of employing erythrosine a suitable basic red dye were used, a separation of the dyes would not occur, and the after sensitising of the paper would be rendered superfluous. John Henry Smith, Wolleshofen, Zurich, and Waldemar Merckens, 1, Schwarzwaldplatz, Mülhausen, Elsass, Germany.

**BLEACH-OUT COLOUR PROCESS.**—No. 7,217, 1907. The present invention is based upon the property of the basic dyes of wandering out of a layer of moist gelatine or analogous substance for which these dyes have little affinity into a layer of nitrocellulose or analogous cellulose derivative possessing a strong affinity for the basic dyes.

The simplest method of applying this invention is to copy a photographic negative upon a sensitive bichromate of gelatine film, and after developing the film with hot water to place it in a solution of basic dye. After the gelatine relief has imbibed a sufficient amount of the dye, the superfluous dye is washed off under the tap and the surface dried with blotting paper. The coloured gelatine relief is then squeezed into contact with the collodion surface intended to receive the finished print, and when sufficient dye has wandered into the collodion (which may be seen by raising a corner of the paper) the surfaces are separated. Under ordinary conditions a few minutes are sufficient for the transference of the picture. The gelatine relief may be employed over and over again, and if three bichromate positives are made from a set of three-colour negatives and transferred in their corresponding colours and in register upon the same celluloid surface a three-colour print in natural colours will be obtained similar to the pinatype process, but with much saving of time. John Henry Smith, 417, Seesträße, Zurich, Switzerland, and Waldemar Merckens, 1, Schwarzwaldplatz, Mülhausen, Elsass, Germany.

**PHOTOGRAPHIC PLATES.**—No. 7,885, 1907. The invention is a method of producing perceptible signs or marks on the sensitive side of photographic plates or films consisting in making incisions or cuts on the sensitive side along the edges of the plates or films. P. A. Newton, 6, Breams Buildings, London, E.C., for the Lumen Gesellschaft mit beschränkter Haftung, 17, Ostra-Allee, Dresden.

**CHANGING BOXES.**—No. 28,868, 1906. The specification describes a changing box for the description of which the nine drawings of the working parts are necessary. A. J. Boulton, 111-112, Hatton Garden, London, E.C., for Edouard Streiff, 37, Rue Lhomond, Paris.

**DIAPHRAGM SHUTTER.**—No. 95, 1907. This invention relates to certain improvements in the photographic shutter, for which an application for Letters Patent was filed dated February 3, 1906, No. 2,713. ("B. J.," March 8, 1907, p. 180.) The shutter is mainly designed for the use of professional and advanced amateur photographers. For the purpose of placing it also in the hands of the large number of less practised amateur photographers, and adapting it for smaller-sized cameras, kodaks, and the like, it has been found necessary to change the driving mechanism of the flies, to improve the special construction of the flies so as to render them more permanent, to enclose the operating mechanisms of the shutter, and to introduce a speed-indicating ring.

For this purpose the invention consists of a photographic shutter in which several flies are pivoted to and operated by a driving-ring in connection with stationary pins applied to the shutter case, the pins engaging slots in the flies located in the centre line of the same. The invention consists further of the construction of the flies themselves; next, of a covering-plate to prevent the ingress of dust, and of a speed indicating ring; and, lastly, of certain additional details of construction by which the operating parts of the shutter can be set and adjusted from the outside of the cover. Gustav Dietz, Lincoln Park, Washington Avenue, Yonkers, N.Y., U.S.A.

**BROMIDE PRINTER.**—No. 2,049, 1907. This invention has for its

object an apparatus which allows the rapid and uniform printing of positive photographs obtained by gelatino-bromide.

The apparatus includes a closed box containing electric lamps under a thick glass supporting the negatives, upon which the bromide paper is placed. The pressure necessary for the contact of the paper on the negatives is obtained by means of electro-magnets, which draw the cover downwards, such pressure as well as the ignition of the lamps being effected by a distributor of electric current so constructed as to be capable of causing the time of exposure to be easily varied according to the negatives to be printed and the rapidity of the paper used. Adrien Cottillon, 11bis, Rue Duchesnay, Asnières, France.

**TELEPHOTOGRAPHY.**—No. 8,727, 1907. A further patent connected with Dr. Korn's system of transmitting photographic images by electric connection. The method of telegraphically transmitting photographs and the like with the aid of synchronously running platen-rolls at the sending and receiving stations, which consists in circulating a current in a sending circuit with a sending selenium cell and compensating selenium cell, of which cells the sending one is exposed to a pencil of rays of light passing through the original and the compensating selenium cell is exposed to another pencil of rays of light under the control of a galvanometer with an interceptor, so that the current is modified by the sending selenium cell and a part of the modified current conducted from a juncture between the two cells through the galvanometer is practically freed from the influence of the inertia of the sending selenium cell, and in conducting the so corrected current from the galvanometer over the line of transmission by operating a photographing device at the receiving station in harmony with the tones of the original. Arthur Korn, 1, Hohenzollernstrasse, Munich.

Owing to pressure on our space the complete specification of View Finder No. 2,356, 1907, of the Rathenower Optische-Industrie-Anstalt, vorm Emil Busch, Rathenow, Germany, is obliged to be held over till next week.

## New Trade Names.

**SEMAPHORE.**—No. 295,758. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. John E. Williams and Co., 109a, Lower Moss Lane, Manchester manufacturers. August 23, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Autochrome Plates under Modified Treatment.

The "Amateur Photographer," in its weekly page, "Colour and the Photograph," thus continues its further instruction in the use of the Autochrome plates:—"We may briefly indicate variations in treatment likely to be of service in special cases, these variations becoming easily practicable in connection with the successive use of a rather strong chrome alum bath and formalin bath, as described last week, the use of either of these hardening baths being always preceded by washing and followed by washing, so as to avoid compensation by contamination of solutions with traces of each other. The negative produced in the first instance, or by the first development may be worth completing in many cases for reproduction or experiments on reproduction, but it is liable to be fogged, in which case as soon as the fixation is complete, a little solution of potassium ferricyanide should be added. This makes the hypo dissolve away an even layer of silver from the film, or "cut" it, as the professional terms the operation. Ordinarily 10 drops of ferricyanide potassium to each ounce of the fixing bath (ordinary plain hypo bath 1 and 5) will suffice. As the film clears it will show as a positive by reflection on the blackish screen, and at this stage the operation should be stopped. Intensification after a thorough washing and use of the E solution may then be carried out by the physical catalytic method, as prescribed by MM. Lumière, or by the mercuric chloride method. When an Autochrome positive is made, and ordinary sequence of operations is followed, the above-mentioned "hypo" and ferricyanide bath may be used at any stage, and

may be followed by either method of intensification. Further, the finished and dried Autochrome, if not varnished, may be "cut" or reduced as above, and re-intensified; proceedings which in many cases result in notable improvement.

## New Books.

"Atlas of Absorption Spectra." By H. S. Uhler and R. W. Wood. 59 pp. and 26 plates. The Carnegie Institution of Washington.

To aniline dye users there are already existing two valuable works, which give graphic representations of the absorption spectra of numerous dyes. These are by Formánek, and are in German, as is also the late H. W. Vogel's work on spectroscopic analysis, in which are included numerous valuable absorption spectra of aniline dyes. So far as we are aware, there is no English work devoted to this particular subject. We welcome all the more heartily therefore the present work, and the only regret we have is that it does not include even more than it does. This is not meant in any disparagement of the work, but it is obviously so valuable that one would naturally wish to see all the aniline dyes thus treated.

Formánek's work, to which we have alluded, is marred by the fact that the plates are drawn by hand from work with a prismatic spectroscop, to the dispersion of which one has no clue. In the plates in this work we have collotype reproductions of actual negatives, taken with a concave or diffraction grating, and to add to their value the spark spectrum of an alloy of cadmium and zinc in air is superposed, as is also a wave-length scale above each spectrum.

Every substance has been examined in three different thicknesses of solution, and therefore one has a complete guide to the absorption with increasing or decreasing strength. The text deals with the instruments used, the methods adopted, and a clear explanation of how to read the results. This is followed by a verbal description of each plate, which gives one at once a clear grasp of the picture, and it is rendered all the more valuable in that the commercial and chemical names and makers of each dye are appended, with the length of the solvent used.

The authors state that the chief object of the work is "to furnish graphical representations, on a normal scale of wave-lengths, of the absorption spectra, both in the visible and in the ultra-violet regions, of a reasonably large number of compounds. The most obvious use of which such a collection can be put is the production of colour greens for photographic work or for removing higher orders of spectra from the first order, in the case of diffraction gratings." When we state that there are no less than 160 dyes thus treated, besides some chemical compounds, such as the bichromates, permanganates, etc., it will be at once conceded that the work will become classic authority on the subject. The only possible regret we have is that the authors were limited by the sensitiveness of the plate used to 6500 in the red, but as their researches extended in the ultra-violet to close on 2000, this may be excused.

"The Romance of Modern Photography." By Charles R. Gibson. 345 pp. 7½ in. x 4½ in. (London: Seeley and Co.) 5s.

The first three chapters of this "popular" book on photography and its applications are devoted to an account of the circumstances attending the invention of a process for fixing the action of light, and remarkably clear, interesting, and accurate account it is. Mr. Gibson has evidently been at pains to acquaint himself with what has been written as the share of Niepce, Daguerre and Talbot in the "discovery" of photography, and though he quotes no authorities, it is easy to see that he has not taken for granted the accounts, usually abounding in errors, which less conscientious writers have given. Moreover, to write agreeably on the history of photography is not easy if one wishes to avoid giving a false impression of what took place between 1839 and 1841. Mr. Gibson's chapters provide as readable and reliable an account of these early days as we know—and we have read them all.

Our author, however, has soon had enough of the historical treatment of photography, and having discoursed of Daguerreotype and albotype in Chapters I. and III. he takes one Broddingnagian stride in instantaneous photography, and the cinematograph in Chapter IV. Having settled down in modern photography he next introduces colour photography in the shape of the Ives Kromsköp process, gives

us a glimpse of the Joly screen, and by this route arrives at the subtractive triple process of Sanger-Shepherd. We may not be able to commend the route, but he is nevertheless an interesting companion on the journey. Thence he arrives at the Lippmann interference process, and at last comes to speak of the bleach-out paper of Dr. Smith, which he has tried for himself.

The making of tone and half-tone printing blocks is a preliminary to other photo-mechanical processes, after which we swerve back again in Chapter X. to colour-photography in its application to printing. Thus half the volume has now been taken up, and we are "moved on" to photography and the criminal in Chapter XI., in which Mr. Gibson's historical aptitude again peeps out in the reference to a positive of Scott Archer's of four thieves (one described as a "dirty thief"), which is alluded to as the first photograph made for purposes of the identification of criminals. This leads our author to compare photographic methods with finger print methods, and to point out that the latter is but an accessory to the former.

The X rays provide Mr. Gibson's next chapter of romance, from which to radio-activity and the photographic action of the extreme of the spectrum is a natural transition. Photo-micrography affords our author an opportunity for an interesting chapter, after which some experiences in flashlight photography in a coal mine, taking a whole chapter for the telling, appears unduly spun out. A good description of Professor Korn's method of photo-telegraphy forms Chapter XVII., following which the author swerves back to elementary matters of the eye and the camera, and stereoscopic vision. Even more irrelevant to other portions of the volume is the miscellaneous Chapter XVIII., which discourses on the large photograph made a year or two ago by the Rotary Co. of telephotography, of photographs of timid and wild animals, and of "faked" photographs. The prominent fault of the book is its lack of arrangement. The author's idea of providing his literary fare appears to be that of Little Jack Horner of the nursery rhyme. He has a goodly stock of plums in his pie, and pulls out one after another without any particular reason for the order being discernible. That is the only charge that can be brought against his work, which is remarkably free from slips, and is moreover "produced" in the handsome shape which makes it fitting for a Christmas present.

## New Apparatus, &c.

The "Jupiter" Instantaneous Electric Lamp. Sold by John J. Griffin and Sons, Limited, Kingsway, London, W.C.

We briefly referred to this new lamp a month or two ago on its introduction into London from the Continent, where it has obtained a great vogue among photographers of all classes, including the very highest. Since then we have had the opportunity of seeing more of its performance in the extemporised "studio" arranged by Messrs. Griffin, who are supplying the lamp and all information regarding it to photographers in the United Kingdom.

The lamp differs from other systems of electric installation in the fact that the light is produced by a brilliant flash across a pair of arcs at an intensified voltage. The whole series of operations by which this is produced is automatically performed by the lamp mechanism, and follows on the operator pressing a pneumatic bulb at the camera. The mechanism consists of a small switch panel, upon which are mounted a pneumatically operated trigger and an electrically operated contact-maker. Upon the back of the panel is fixed a lever arm and series of contact studs similar to an ordinary motor-starting switch, the switch-arm being under the control of a strong spring. In action this device behaves as follows: The pressure of the bulb releases the trigger controlling the switch-arm, which then, under the influence of its spring, flies across the contact studs. As soon as the contact is made, the solenoid in the centre of the panel becomes "excited," and the core, which carries a short carbon rod, is forced up against a similar carbon contact, and the greater portion of the arc lamp resistance is cut out. The effect of this is to increase the voltage across the terminals of the arc lamp while the switch-arm is passing across the contact studs, and the arc therefore blazes intensely for a small fraction of a second. As soon as the switch-arm has passed the contact studs the arc circuit is resumed through the resistance.

The great brilliance of the flash is responsible for a high development of actinic light, whilst the shortness of its duration precludes the liability of a sitter to move during an exposure, for the simple reason that the exposure is so rapid. The light, however, is not of such extraordinary apparent brilliance as to disturb a sitter of whom a series of exposures are being made, and the arcs are, as will be seen from the figures, shielded by a conical frosted glass screen, and further by a silk or muslin screen placed between them and the sitter.

Fig. 1.

Fig. 2.

The lighting is thus greatly softened, yet the intensity of the light is such that with a plate of not the highest rapidity a lens aperture of  $f/11$  to  $f/16$  was found sufficient for a full exposure. This great power was demonstrated to us by Messrs. Griffin, who inform us of their readiness to make appointments with photographers and their assistants at the Kingsway premises.

Fig. 3.

It will be understood that the actual flash occurs at the moment of exposure. For focussing a series of incandescent burners are provided round the arcs themselves. They coincide practically with the diffused light which the arcs themselves emit, so that the effect on the focussing screen may be taken as that which is obtained on the plate.

For all classes of professional portraiture, and for that of children in particular, the lamp should prove most valuable. We reproduce

a couple of photographs taken with it to illustrate its uses for subjects which are not easily obtained with anything but a very short exposure. They are typical of hundreds which every photographer would wish to take by artificial light, and which are easily within the range of the "Jupiter" installation. Artificial lighting as our readers know, is one of the factors which in our belief is

Fig. 4.

rapidly altering the practice of professional portraiture, and, the being so, it behoves every professional worker to keep himself fully informed of the new facilities at his disposal.

Messrs. Griffin have in readiness a small budget of literature dealing with the new lamp, the information in which is to be obtained by applying to them at Kingsway, London, W.C.

## New Materials.

Photographers' Printing. Produced by H. Hood and Co., Ltd., Strand, London, W.C.

Messrs. Hood are fortunate in the relations they can establish with photographers. Being makers of blocks, as well as printers of them, they are able to prepare half-tones or zincos of the quality most suitable for a given job, and at the same time have the responsibility for their effective behaviour in the press. Given a photograph which is right in the first instance, the whole credit or the whole blame for the execution of an order rests on them, and is a responsibility which we know to be very cheerfully undertaken by the firm. Messrs. Hood, in sending us a large selection of their current work, remind us of the effective use which can be made of half-tone reproduction in photographers' stationery and note headings, but their claims upon the photographer's notice are not limited by the use of half-tones, since designs in line, wash, and engraving are branches of their business in which they turn out consistently good work. Of the large selection of recent work which they send us we should like to refer particularly to the postcards and view books, produced from first to last at the Hood works from a customer's photographs. The demand in postcards being now all for colour, the three and four-colour work

Messrs. Hood, which is done at very reasonable prices, should permit any photographer to use his own negatives in competing with the cards of the large houses. We may mention that a coloured original is not a necessity for a coloured postcard, and although Mr. Hood himself is a practised three-colour worker and an exhibitor in the collection of Society of Colour Photographers, three-colour photography, in the strict sense of the term, is not a vital preliminary to the issue of postcards in colour. More ambitious work in the way of souvenirs and advertisement brochures are also a strong specialty. Messrs. Hood, with whose aid a photographer entrusted with the preparation of the photographic illustrations for any large publicity scheme might safely undertake the supply of the complete production.

"Autotrans" Frames (for Autochrome Transparencies). Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W. The firm of Fallowfield, with its accustomed enterprise and with peculiar appropriateness, enters what is assuredly a fallow field—namely the supply of accessories for the Autochrome process. Messrs. Fallowfield respond to the first and immediate demand of the Autochrome maker by offering a suitable frame for the transparency. This takes the form of a plain oak frame which gives a border of one inch to the glass and allows for the introduction and removal of the Autochrome at a loose end, which is slipped into place and secured by a touch of gum or a small brass screw. The Autochrome is thus held in a

ove, and even if not protected by a cover glass is out of harm's way. Moreover, the frame provides a much higher degree of safety on the transparency is sent by post. The prices of these "Autotrans" frames are as follows:— $4\frac{1}{2} \times 3\frac{1}{2}$ , 4s. per dozen;  $6\frac{1}{2} \times 4\frac{3}{4}$ , 8s. per dozen;  $8\frac{1}{2} \times 6\frac{1}{2}$ , 10s. per dozen;  $9 \times 12$  c/m, 6s. per dozen;  $13 \times 18$  c/m, 9s. per dozen. With each frame are supplied two small metal hooks which can be attached to the side or end for position in a window. Messrs. Fallowfield are also making a specialty of supplying carriers for the foreign sizes of plates at the following prices:— $5 \times 4$  to  $9 \times 12$  c/m, 1s. each;  $6\frac{1}{2} \times 4\frac{3}{4}$  to  $9 \times 12$  c/m, 1s. 6d. each;  $8\frac{1}{2} \times 6\frac{1}{2}$  to  $13 \times 18$  c/m, 2s. each;  $10 \times 8$  to  $18 \times 24$  c/m, 6d. each.

"Academy" Mounting Papers and Boards. Sold by "Bartons," 114, Golden Hillock Road, Birmingham.

or variety of colour and of surface and for different substances material, the mounting papers and boards of this firm are as comprehensive a series of materials as we have seen. A set of specimens of the newly-issued colours and textures has surprised us by the choice of the disposal of the photographer. The papers are obtainable, as sheets, in sheets 20in. x 25in., of five different substances, the "thin" for pasting down or dry mounting, and the thicker makes for re-partout and cut-out mounting. In particular we would signalize "negligé" and "canvas" surfaces, and the pebbled paper, sold "craftsman"; but mention of one or two is invidious when the attention is so great. Any desirous of gaining all possible effect in mounting, and particularly in dry-mounting, may be advised to send Messrs. Bartons for samples of the papers and boards.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 11.

West London Photographic Society. Annual Meeting.

MONDAY, OCTOBER 14.

Kidderminster and District Photographic Society. Annual Meeting.  
Lancaster Photographic Society. Exhibition of Lantern Slides.  
Bradford Photographic Society. "Lantern Slide Making." W. H. Reed.  
Stafford Photographic Society. "The Camera and How to Use It." F. Cliff and H. Hey.

TUESDAY, OCTOBER 15.

Leeds Photographic Society. "Round the World with a Camera." Edgar Lupton.  
Blairgowrie and District Photographic Association. "A Cycling Tour Among the Dolomites." Rev. J. Hunter.  
Redhill and District Camera Club. "Experiences of a Photographer in the Tropics." A. H. Dunning, F.R.G.S., F.R.P.S.  
Sheffield Photographic Society. "Photography of Flowers and Fruit." E. Seymour.  
Manchester Amateur Photographic Society. 1906 Affiliation Competition Slides.  
Birmingham Photographic Society. "Colour Photography." H. J. Comley.

WEDNESDAY, OCTOBER 16.

South Suburban Photographic Society. "Pictorial Composition." J. T. Ashby, F.R.P.S.  
Coventry Photographic Club. "Norway." B. B. Dickinson, M.A., F.R.G.S.  
Croydon Camera Club. Lantern Night.  
Evertown Camera Club. "Glimpses of Erin." J. M. Dallahan.  
Leeds Camera Club. "Are Orthochromatic Plates Best for Landscape Work?" J. W. Charlesworth.

THURSDAY, OCTOBER 17.

Queen's Park Amateur Photographic Association. "The Movements of a Camera." James McKissack.  
Liverpool Amateur Photographic Association. "The Evolution of an Amateur Photographer." Willis Brunt.  
Midlothian Photographic Association. "Woodland Photography." Dan Dunlop.  
Hall Photographic Society. "The Land of Carillons, Canals and Coifs." C. B. Howdill.  
North London Photographic Society. "Carbograph." Rotary Co.  
Handsworth Photographic Society. "My Experience of the New Autochrome Plates." T. Haynes Duffell.  
Richmond Camera Club. "Some Gleanings from Africa During the Visit of the British Association for the Advancement of Science in 1905." J. H. Gardiner.  
London and Provincial Photographic Association. "Hints to would-be Patenteers." W. J. Ferry.

### ROYAL PHOTOGRAPHIC SOCIETY.

ORDINARY meeting, held October 8, 1907, at the New Gallery, the president (Mr. J. C. S. Mummery) in the chair.

The medal awarded to MM. Lumière was presented to Mr. T. K. Grant: that awarded to Professors Lowell and Lampland is to be forwarded to them.

"The president delivered his annual address on "The Position of Pictorial Photography." He pointed out that the very early workers were apparently devoted to detail alone, and that David Hill was the pioneer of purely pictorial work, his results being quite up to the best results of to-day.

At the first meeting of the Royal Photographic Society a paper on "Art" was read by Sir W. J. Newton (an artist), but the progress of pictorial photography was very slow, in spite of the examples set by Hill, Newton, Rejlander, H. P. Robinson, and Mrs. Cameron. At the present day photographers were more or less divided into two important groups of specialists—the pictorial and scientific groups.

Training was essential to pictorial photography, and though very much was due to the amateur, it is really the professional, who devotes the whole of his time to practice and study, to whom we should look for the highest class of work. Art training as at present available, though perhaps suited to painters, was not exactly the best for photographers. Possibly in time a more suitable system might be devised.

In reference to colour work, the speaker observed that the recent remarkable advances in colour transparency processes rendered it probable that a suitable paper process would soon be forthcoming, in which case the pictorial possibilities of colour photography would have to be seriously considered and studied, while the photographer's training would have to be modified and extended.

No discussion is usual after the president's address, and in accordance with this custom the meeting terminated with a unanimous vote of thanks to the president, proposed by Rev. F. C. Lambert and seconded by Mr. E. T. Holding.

CROYDON CAMERA CLUB.—At the invitation of the club Mr. Ernest Webster, of Messrs. Rogers and Webster, gave a practical "talk" on the mounting and framing of photographs, interspersing his remarks

with candid and highly diverting criticisms, and observations on photographic matters generally. Without going so far as to suggest that Mr. Webster regards pictorial masterpieces as consisting of frames with something in the middle, yet, on the other hand, it cannot be said that he looks upon the setting of the gem as in any way secondary or of minor importance. There was no doubt, he said, that carbon was the process. Carbon prints with thin, deep, juicy tones required large massive frames, eminently satisfactory from all points of view, and in particular that of the frame maker. Dainty platinotype prints should be handled more delicately, and a light frame, in the nature of a grey slip, harmonised well; but it was difficult to get a permanent grey, as paint must not be used. In this connection Mr. and Mrs. Cadby had been very successful, on lines which many had tried to imitate, but unsuccessfully. Personally he did not favour these narrow slips, with the tendency for the glass to fall out of the frame; besides, they were not commercial. He was astonished to find, from examples handed up, that platinotypes could also be made of rich sepia colour. These would require much the same treatment as carbons. The bromide process was no good, absolutely no good; it failed to give fine gradation or tone. Gum had its points, and he wished it would progress; large prints were desirable. A clever young worker, named Arbuthnot, had made some excellent artistic pictures, but he had now dropped out of "gum" and into "oil." Speaking of framing in general, British oak was satisfactory, and, moreover, cheap, it being imported in large quantities, duty free, from America. Walnut was better, and more expensive. Some walnut wood was, however, not safe to use, owing to its tendency to warp. Shaped and panel frames were away from the stick-in-the-mud style, and they might be ornamented in relief. In either case they isolated the exhibit from its neighbours, and gave it prominence thereby. If a picture had a predominant note on one side it might be placed near to a top corner of the panel piece, balance being secured by the extra length of the panel in the other direction. He was glad to see that natural colour woods, stained and oiled, had apparently killed the wide deal frames painted dirt colour, so much in vogue in the past. Mr. Webster finally illustrated how frames were made, and suggested various harmonious arrangements for mounting and framing a large number of prints handed up. We understand that Mr. Webster is open to consider applications to give his chatty discourse before societies in London and neighbourhood. He certainly afforded an amusing and instructive evening at Croydon.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—The first meeting of the autumn session of this society was held at Plough Hall, High Street, last week, Mr. A. Haddon in the chair. About eighty members and friends were present. Mr. F. J. Mortimer, F.R.P.S. (editor of the "Photographic News"), delivered a lecture on "Cash and the Camera," illustrated by a large number of lantern slides very successfully shown by Mr. P. B. Dannatt, who provided and worked the lantern for the occasion. Mr. Mortimer explained very fully "How it is done," pointing out the absurdity of sending to a particular editor pictures which have no interest for his readers, though they might be excellent material if sent to another and more suitable paper. No man would send a consignment of fish to a butcher or of meat to a fishmonger and expect to sell his wares. What the average editor wanted was photographs of events of interest to his special readers, and these of a newsy character.

**BATH PHOTOGRAPHIC SOCIETY.**—The annual meeting of this society was held last week, when it was stated that the membership at the close of the season was 95. A good programme of meetings had been arranged and carried out almost entirely by the members. It was further stated that during the year an important agreement had been entered into by the President with the Royal Literary and Scientific Institution, whereby members now had the use of the dark room and Selborne room for a term of five years. The financial statement showed a small deficit owing to extraordinary expenses having to be met during the first year; but several members present contributed special donations, and it is hoped by this means to wipe off the debt. The officers for the ensuing session were elected as follows:—President, Mr. Mowbray A. Green, A.R.I.B.A.; vice-presidents, Rev. Jas. Dunn, Dr W. H. Symons, Mr. Walter Pitt, Mr. Geo. F. Powell; Council—Dr. J. Hardyman, Dr. R. A. Bayliss, Messrs. W. H. Weeks, Walter Rossiter, Walter E. Cooline G. B. Caple, Fred Stone, and G. L. Dafnis; hon. portfolio secretary, Mr.

F. H. Gray; hon. financial secretary, Mr. J. Lewis; lanternist, Mr. F. Ging; and general secretary, Mr. W. J. Hallet, M.P.S.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on October 3—Mr. Teape in the chair—Mr. A. E. Smith lectured upon and demonstrated "Bichromate Printing." He had, he said, noticed that a green carbon tissue always required long soaking before transfer than any other colour; it was also longer in developing. He had tried special sensitising solutions, but always went back to the plain 5 per cent. solution of bichromate as being the best. The lately exploited spirit solution in his hands was very liable to show streaks in the finished print. The negative for carbon should be denser than for P.O.P. printing if good results were wanted. Carbon, he thought, was the finest of all our printing processes, but it could not be hurried, and for beautiful effective prints he recommended warm black, and the transparency black tissues. Printing he did with an arc lamp at 12 inch in 1½ minutes. Following on with the preparation of transfer prints for litho work he demonstrated the development and making up of the print ready for transfer to the stone, showing that the ink only took to the print not acted upon by light. This he followed by demonstrating the dusting-on process, and said he used a mixture of glue, glucose glycerine, and water, with bichromate, coated and dried the plate and printed whilst the plate was hot and dry. When moist the print became sticky and the powdered colour, upon being applied with a camel-hair brush, stuck to the print where the light had not acted. This process, he said, was very useful for making reverse negatives and other purposes, as when it was finished, if coated with collodion, it could most easily be transferred to any object. He finally demonstrated an entirely new process of gum printing which largely interested every member at the meeting, and of which the Association expects to hear more in the near future. A vote of thanks, proposed by Mr. Freshwater, brought the meeting to a close.

**HULL PHOTOGRAPHIC SOCIETY** opened the winter session last week with a social function. The secretary (Mr. F. J. Webster), in conjunction with Dr. Divine, submitted quite a number of Autochrome plates with varied subjects, flowers and fruit being much in evidence; whilst the portraiture studies were extremely successful, being taken out of doors. The Doctor's kindness in bringing his microscope to carefully examine the plates before exposure and after was much appreciated. The Rev. C. O. Stewart also submitted his results, which were simply charming, and also called for much attention. The President, in a very enthusiastic manner, called special attention to the new plates, and thought it was probably the beginning of greater things in this all-absorbing branch of photography—the possibility of being able to take a subject by direct exposure. He thought that photography as an art had a distinct influence upon the amateur, and taught him first to appreciate light and shade and train the eye in a remarkable way. The amateur finds his next step must be one of the study of balance of this light and shade, and it is not long before he finds out that colour or tone plays an important part in one's results, and makes one see the colours in landscape as he never saw them before the commencement of his photographic days.

**MESSRS. B. J. EDWARDS AND Co.** write us that they have been awarded the gold medal in the photographic section of the International Sports Exhibition held from July to October at the Grand Palais des Champs Elysées, Paris.

**SOUTHEAST TWENTIETH ANNUAL PHOTOGRAPHIC EXHIBITION.**—The exhibition will be held from November 29 to December 5 inclusive, entries closing on November 20. There are two open classes, Class A for framed prints, any subject, and Class B for lantern slides, any subject, with ten silver vases, 8in. high, as awards. There will also be a class for residents in Hants and Isle of Wight only, with ten silver vases as above as awards. The judge is Mr. H. Snowden Wax. The exhibition will be held as in former years in conjunction with those of Southampton and Hove, the former opening on November 1 and the latter closing December 14. Pictures exhibited at all three exhibitions will be forwarded from Southampton to Southsea, and from Southsea to Hove free of charge. The exhibits in the Hants and Isle of Wight class will be forwarded free of charge from Southampton (which exhibition has a similar class) to Southsea. Entry forms apply to Gilbert Wood, 10, Pelham Road, Southsea.

## Commercial & Legal Intelligence.

**A MORECAMBE BANKRUPTCY.**—The difficulties of a Morecambe photographer and tobacconist, named Alfred Ernest Edward Clay Poole, 9, The Crescent, and Midland Studio, Northumberland Street, were revealed at his public examination in bankruptcy at Preston on October 4. His gross liabilities were £284 3s. 1d., of which £190 13s. 1d. is expected to rank for dividend, and the deficiency was £142 8s. 7d. Debtor alleged as the cause of failure "losses in connection with guarantees, bad trade, keen competition, and heavy expenses." He stated, in reply to the Official Receiver, that he commenced business in Morecambe as a photographer twenty-five years ago with a capital of £100, which he borrowed, and five years afterwards started a tobacconist's business. In May, 1899, debtor, with three other directors of the Morecambe Theatre Company, became guarantors to a bank. In March, 1901, he again became guarantor to the same bank. He was called upon for payment under guarantees, and in March, 1906, in order to avoid legal proceedings, he conveyed a dwelling-house, costing £500, in Morecambe, to the bank in settlement of their claim. Debtor said up to the time he was called upon to pay on the guarantee he was quite solvent. The business has been gradually losing for three or four years. Mr. Fawcett, Morecambe (for debtor): But for your unfortunate associations with the Morecambe Theatre Company you would have been quite solvent?—Yes. You parted with a house of the value of £500, and invested £140 in shares?—Yes. Your deficiency account is £142, and so but for that transaction you would have been £500 to the good?—Yes. The examination was adjourned.

**A NORTHERN BANKRUPTCY.**—The statement of the affairs of Frank Scott Russell, lately trading as a photographic dealer ("Scott, Russell and Co."), at 13, Albert Street, and 54, Martineau Street, Birmingham, Scarborough, and Sheffield, as filed by the debtor disclosed liabilities amounting to £1,432; assets, 501 shares in Scott Russell and Co., which are estimated to produce nothing. Mr. G. H. Acheson (Deputy Official Receiver) presided at the first meeting of creditors held last week. In his observations, Mr. Acheson stated that prior to October, 1901, the debtor was employed as a traveller in the foundry and fire-brick trade, and that he held other agencies, including one in the pictorial postcard trade. At that date he commenced business on his own account in Birmingham as a photographic dealer, with a capital of £20. In March, 1904, he opened a branch business at Scarborough, and in February, 1905, he opened other premises in the town. In October, 1905, he opened a wholesale warehouse in Sheffield, but in December, 1906, that warehouse was closed, a similar one having been opened in March, 1906, in Albert Street, Birmingham. Debtor, who was trading under the style of "Scott Russell and Co.," did not appear to have taken proper steps to ascertain the result of his trading, and whether the same had been carried on at a profit or loss. The unsecured liabilities included £1,336 ordinary trade debts and £85 bank overdraft. The case was a summary one, the Official Receiver being appointed trustee.

### NEW COMPANIES.

**W. D. MORRIS.**—£500 (£1). To acquire the business carried on at 246, High Road, Willesden Green, N.W., by W. D. Morris, and to carry on the business of wholesale and retail druggists, chemists, dealers in photographic, scientific, and other apparatus and materials, etc. No initial public issue. W. D. Morris is the first general manager. Qualification, 100 shares. 246, High Road, Willesden Green, N.W.

**WILLMONTS.**—Capital, £2,000 (1,000 £1 preference and 2,000 10s. ordinary). To adopt an agreement with H. de Montin for acquisition of his connection in business of photographer and photographic printer, etc. No initial public issue. Registered without articles.

**THE UNITED STEREOSCOPIC SOCIETY.**—The result of the landscape competition of this society, judged by Mr. A. Horsley Hinton (Editor of "The Amateur Photographer"), was as follows:—1st award, T. H. Pettipher; 2nd award, A. J. Snow; 3rd award, A. T. Mole; hon. mention, Messrs. F. Low, H. A. Miles, F. W. Pearson, and H. S. Targett.

## News and Notes.

**PHOTOGRAPHIC LECTURES, NEWCASTLE.**—The council of the Newcastle-upon-Tyne and Northern Counties Photographic Association announce that the headquarters of the Association are now located at the Armstrong College, Newcastle-upon-Tyne. By special arrangement with the council of the college a course of lectures on the optics and chemistry of photography will be given at the college during the ensuing two winter terms, commencing on Thursday, October 10. The first part of the course, that on the "Optics of Photography," will be delivered by Professor H. Morris-Airey, M.Sc., who will deal with the following subjects:—Experiments to demonstrate some important properties of light; the prismatic spectrum; actinic and heat rays; the single lens, why unsuitable for photographic work; development of the compound lens; the function of the diaphragm; size and intensity of the image; depth of focus and perspective; achromatically corrected lenses; distortion of images; explanation of the design of the following lenses—1, Portrait; 2, Wide-angle; 3, landscape; 4, telephoto; historical survey of the subject. This course commenced on Thursday, October 10, and will be continued each Thursday evening between 8 and 9 p.m. until December 12.

The second part of the course, that on the "Chemistry of Photography," will be delivered by Professor F. C. Garrett, D.Sc., F.C.S., who will deal with the following subjects:—

Chemical compounds and some of the changes which they undergo; chemical change and the laws which govern it; the meaning of a chemical equation; some important chemicals used in photographic work; silver and its salts, the halogens; the action of light upon compounds of the metals; the chemical action of developers and of restrainers; fixing the picture; intensifying and reducing the negative; the preparation of a print and the changes brought about by the use of toning solutions; the carbon process; bichromate printing processes. Particular attention is called to the fact that this course, which will consist of ten lectures, will commence on Tuesday, January 7, 1908, at 8 p.m., and will continue each Tuesday evening between 8 and 9 p.m. until March 10.

The fee for the full course is 10s. 6d., and those who desire to attend the lectures should enter their names at the Secretary's office at the college either by personally attending there or by letter addressed to Mr. F. H. Pruett.

The Newcastle Association may be congratulated on its enterprise in arranging these courses of lectures, which it is hoped will be attended by photographers on the Tyne.

**ARCHITECTURAL PHOTOGRAPHS.**—A short description of the Bristol cathedral organ, published in connection with the series of recitals now being given, contains, we notice, a number of very good photographs by Mr. Charles H. Horton, of Bristol, whose business has been specially in architectural and technical photography. We are glad to commend such excellence of work when we observe it.

**PHOTOGRAPHY IN COLOURS—NEW EDINBURGH SOCIETY INAUGURATED.**—With a membership of about a hundred, the Mid-Lothian Photographic Society was inaugurated in the Goid Hall, Edinburgh. Dr. Drinkwater, the president, occupied the chair, over a good assembly of members. Mr. E. L. Brown contributed an interesting paper on the Autochrome process of direct colour photography in one operation. Mr. Brown, whose lecture was illustrated by negatives of his own taking, drew attention to the fidelity of coloration. It was to be regretted at present, he said, that results had not yet been committed to paper, but only to glass. He understood, however, that there was a paper in course of preparation which would allow of prints being taken.

**THE "RAJAR" CAMERA** offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to A. J. Hollingum, Leicester Road, Wanstead, having been judged the best print received during September. The paper on which the print was made was purchased from Mr. G. F. Horne, 32, Gracechurch Street, London, E.C.

**DEVELOPING AUTOCHROMES.**—It may interest a number of our readers to know that Messrs. Jas. H. Sinclair and Co., 3, Haymarket, W., have now opened a department for the developing and finishing

of Autochrome plates. The department will be under the guidance of Mr. James A. Sinclair, who has had very considerable experience with these plates, and every care will be taken to get the best results possible.

R.P.S.—The following lectures will be delivered at the New Gallery:—Saturday, October 12, "Some Dutch Places and People," by Arthur Marshall, A.R.I.B.A., F.R.P.S.; Monday, October 14, "Lakes and Villages in North Italy," by the Rev. H. O. Fenton; Thursday, October 17, "Adventures in Bird Land," by Oliver G. Pike, F.R.P.S.

THE SCIENTIFIC SHOP (Albert B. Porter), of 324, Dearborn Street, Chicago, writing in reference to our note of September last, says: The particular reason why the second order spectrum was taken in estimating the resolving powers of these gratings is due to the fact that grating replicas, as hitherto made, were very deficient in their definition in the second order. All of the Ives gratings, however, have, in the first order, a resolving power about five times that required to show the Nicol line between the D's, and the definition is such that a magnifying power of about 30 diameters is required to utilise their full resolving power.

PHOTOGRAPHS OF ALLIGATORS.—Mr. H. G. Ponting, examples of whose clever and pictorial photography of Eastern scenes have been seen privately in London—one or two are on view at Messrs. Sanger-Shepherd's stall at the R.P.S. Exhibition—contributes to the Paris journal, "L'illustration," an article on his adventures in photographing the alligators in India. His text is illustrated by a large reproduction of himself within a few feet of four huge alligators, with savage eyes fixed on himself and his reflex camera.

TRAILL TAYLOR MEMORIAL.—As previously announced, the tenth annual lecture will be delivered on Tuesday, October 22, 1907, at 8 p.m., at the New Gallery, 121, Regent Street, W. The lecturer will be Mr. S. D. Chalmers, M.A., who will take as his subject "Aberrations in Photographic Lenses."

DR. J. H. SMITH, of Zurich, whose direct printing "Uto" paper is well known to those interested in colour work, informs us that the increasing demand for this material is leading him to abandon the manufacture of ordinary plates and papers and to seek for collaboration in specialising in the colour processes. Dr. Smith makes an announcement in regard to the matter in our advertisement pages this week.

ROYAL PHOTOGRAPHIC SOCIETY.—The Council have decided to purchase Mr. J. C. S. Mummery's "A Winter Landscape" and Mr. Furley Lewis's portrait of Mr. Mummery for the permanent collection of the society.

MR. PIRIE MACDONALD, "Photographer of Men," has opened a new studio in the Howard Building, Fifth Avenue and 47th Street, and will continue the studio, established seven years ago in the Washington Life Building, Broadway and Liberty Street, New York. Mr. MacDonald will make sittings at either place, by appointment.

SOME ANIMATED PICTURES of the present war in Morocco have been taken by the Urban Company's expert operators with the French troops at Casa Blanca, and are now being shown in "Urbanora" at the Alhambra. Many of the scenes have been photographed within the actual zone of fire.

THE "AUTOCHROME" PROCESS.—Owing to pressure on our columns this week we are compelled to hold over the commencement of an article on the "Autochrome" plates by Mr. Arthur Payne, F.R.P.S.

## Correspondence.

### PINATYPE PORTRAITS IN THE COLOUR EXHIBITION. To the Editors.

Gentlemen,—I notice in Mr. E. J. Wall's review of the exhibition of the Society of Colour Photographers, on page 74 of the "Colour Supplement," you mention Exhibits No. 53 M as being the work of Mr. S. J. Beckett. These, I think you will find, are my work, and I shall be glad if you would correct same. Probably it might be of interest to a few of your readers to have further particulars of the process, which is Pinatype, taken during April, with an inclusive exposure in the studio of 15 seconds. The prints exhibited are bona-fide examples of the process, there being no hand work upon them.—Faithfully yours,

ERNEST A. BECKETT.

The Grove, Hackney, N.E.

October 4, 1907.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

A. Russell, 6, Wilde Street, Liverpool. Photographs entitled: "After the Storm," and "Weathering the Storm."

DISTEMPER BACKGROUND.—I have recently made—or, rather, tried to make—a distemper background, and it has turned out a miserable failure, and I should esteem it a great favour if you will tell me why. I tightly strained some unbleached calico on the frame and coated it with size. I then mixed with water some whiting and lamp-black, and then added about an equal quantity of size, boiling hot, and, after thoroughly mixing, I applied it, using a large paint brush, as quickly as I could, and before the mixture got cold. When the background was dry it was all brush marks and quite useless.—FIRST ATTEMPT.

We are not at all surprised that the result was a failure. The distemper should have been applied cold, and only sufficient size should have been used to form a thin jelly when it was cold. Instead of applying the colour with a painter's brush it should be laid on thickly with a whitewash brush. To get an even surface, when dry, requires some little knack. The colour should be laid on thickly and quickly, so as to cover the whole surface before any portion becomes dry, and in no case should the work be gone over a second time, otherwise brush marking will show. Before the background is done again it must be re-sized.

A. SIMCOR.—It is a matter you had better consult a solicitor upon. The agreement, of which you send a copy, is so vaguely worded and clumsily drawn out that we can make little of it. But so far as we can see, you will have to make good the adaptations on its expiry. There seems nothing in the agreement that will exempt you from them.

J. C. FORDLY.—The darkening of the prints by exposure at the railway station is due to their being imperfectly fixed. The whole of the silver salts were not removed from the paper, and they have darkened to the purple tint through the prolonged exposure to the strong light. The fumes from the engines have had nothing to do in the matter.

J. KINGS.—The want of definition is due to the lens not covering the size of plate. An ordinary quarter-plate R.R. must not be expected to cover a full size postcard. Some of the modern quarter-plate anastigmats will, however, do so if they are well stopped down.

COPYRIGHT.—In the spring I took a series of pictures of this neighbourhood and published them as postcards, which have had a good sale. Before publishing them I made most of them copyright. Recently another photographer here has taken identically the same views, and I am told that he actually had my picture with him at the time, so as to get his the same as mine. These he is now selling at 1d. each, while mine sell at 2d. each. Can I come upon him for infringement of my copyright, seeing that he has taken his pictures from identically the same spot as I did mine?—A. Z.

No. You have no remedy. Your copyright only covers your pictures, and not the scenes themselves. Had he copied your

photograph you would have had good cause for action. But as you took his from the scenes themselves you can do nothing.

**HYGEMAT.**—There is not an appreciable gain in  $f/5$  over  $f/6$ , and our present lens is an excellent one. If you must change, we would advise you getting one of still larger aperture, such as one of the new Tessars of  $f/4.5$ .

**GROUND.**—Can you tell me what to use to paint a background dead black? I have several old backgrounds by me, and thought should like to make one of them plain black, and have used vegetable black, mixed with hot water and plenty of size, and it put on while quite hot. This, however, dried a nasty yellow colour and patchy. The background was grey, an exterior tinted on it before. When I found it did not dry black it was given a second coat, with no better result, and then it was sized and given a third coat; but it is just the same, and very stiff and cockled up. Could you tell me what to do to it, and if not, how I ought to paint over one of the others that I have?—me, and what to use? Should I have the side with no painting done, instead of painting over that already done?—B. D. G.

It is evident that there was not sufficient pigment in the dispenser to thoroughly hide the old painting. As the background now have done has become cockled we should advise you to make fresh start with one of the others by giving it a good coating size, applied hot. Then mix the black—"drop-black" is the best convenient to use—with water, so as to have about the consistency of thin cream. Then add sufficient size to form a thin, unctuous jelly when cold. The colour must be laid on cold, using a large whitewash-brush for the purpose. It should be applied quickly, so as to get all coated before any part dries.

**QUERY.**—Will you kindly let me know what would be the best form or shape for studio, built out on brick piers, from first floor of a building, the end of which faces north? Length of 9 ft. 6 in., width of studio 9 ft. I enclose a sketch by the builder, as the easiest and inexpensive way to do it, but in it the roof is a lean-to. I do not think this will answer; but, on the other hand, 9 ft. is hardly sufficient width for a span roof. Could you advise a single span running from the side? And if so, which light would you consider best, east or west, as we can have either?—ALBERT FLINT.

Nine feet wide would be very narrow if you require the studio for professional work. If the studio were of the ridge form you could use both an east and a west light. The latter in the earlier part of the day and the other in the afternoon, so that you would never be troubled with the sun. We should advise you to carry the studio further out than the 9 ft. 6 in., if possible, otherwise when the background end is shaded by the blinds or curtains there will not be much light left to work with. The sketch has not been returned, as requested.

**STUDIO LIGHT.**—Would you kindly tell me if there is a reliable lamp on the market, suitable for full-length portraits, and so, where it could be procured?—ARTIFICIAL.

Adamson's compressed gaslight apparatus will enable you to take full-length portraits. It is supplied by Messrs. Still and Sons, of 24, Charles Street, Hatton Garden, E.C. They will not only demonstrate its working to you if you communicate with them.

**ENLARGING.**—I have lately bought an enlarging lantern, and want to enlarge, etc., from film negatives. Is there any better way of holding those negatives than putting them between two plates of glass? I have tried to get very thin plates but cannot, at any price, locally. Where can I get them? My size is up to  $7\frac{1}{2} \times 5$ .—E. GUBRINS.

There is nothing better for the purpose than two plates of thin glass. We should advise you to get thin "Patent Plate." If you cannot get it in your neighbourhood you can obtain it from Messrs. Hetley and Co., glass merchants, Soho Square.

**FACTORIES ACT.**—As I only employ an assistant and apprentice (both boys) and only do the ordinary routine of portrait photography I do not manufacture or produce goods, such as opalines, etc., I am not liable under the Factories Act. Is it necessary for me to notify the inspector and register my establishment under the Factories Act? Our hours are 9 to 7, 9 to 1 on Wednesdays, and 9 to 9 on Saturdays. Is it necessary, if we should have to work overtime, as we often do, that we are compelled

to give him notice before we do so? I have never yet had a visit from the inspector or received any notification as to my establishment, nor have I yet been in any studio that has done so; but after reading your article in the issue of September 13 I hardly know what is expected of me. A little assistance would be welcomed by—PERPLEXED.

If the two males you employ are over eighteen years of age you need not trouble yourself about the Factories Act, as it does not apply to your case.

**PAPER COATING.**—I am coating paper for a special purpose, and I succeed very well, and it answers all requirements, only it dries out matt. What I want is a glossy paper. What have I to add to the gelatine solution to make it dry out glossy and remain so? The strength of the coating solution used is 25 grains gelatine to every fluid ounce of water. Trusting you can assist me with above information, and thanking you in anticipation.—COATER.

A glossy coating can easily be obtained with the stated strength of gelatine per ounce, provided the paper itself has a glossy surface, as with Baryta surface paper. If this is not the case, then it would be necessary to increase the quantity of gelatine to about 50 grains per ounce, or even more.

**A. E. A.**—We have made inquiries, but cannot hear of anything answering to your description.

**COPYRIGHT.**—We were asked to take a photograph of a northern town ladies' band, who were playing in one of the London parks, on account of a stationer who wishes to issue postcards. The bandmaster gave facilities, and nothing was paid by them for taking the photograph. We presume we can publish the photographs without hindrance and secure the copyright.—DIOCLEDES.

Certainly you cannot. If you were paid by the stationer for taking the photographs the copyright is his.

**SULPHIDE TONING.**—I have recently taken to toning large batches of bromide prints and postcards by the sulphide toning process. (1) Can I vary the colour of the print by alteration of the ferricyanide solution, as I get a nice brown with one kind of paper, whilst on another I get a dirty yellow-brown? (2) How long should the prints be washed after bleaching? (3) How long should the prints be washed after sulphide bath? (4) Is there any book on the sulphide toning process? (5) Do you consider the prints permanent if well washed? I bleach my prints in the following:—

Potass ferricyanide .....	40 grains.
Potass bromide .....	80 grains.
Water .....	10 ounces.

Washing all stains out and darkening in:—

Sulphide of soda.....	24 grains.
Water .....	10 ounces.

After washing a little I place in an alum bath and wash again. If you could give a better formula than this I shall be greatly obliged.—H. M.

(1) Yes, the colour will vary with the proportions of the ferricyanide and bromide, and the results vary also with different bromide papers. We think your formula is not the best. We should prefer more ferricyanide in proportion to bromide, say bromide equal to one-half or one-quarter the ferricyanide. (2) About five or ten minutes, until yellow colour is gone from the whites and a little longer. (3) A quarter of an hour is sufficient. (4) "Toning Bromides," by C. W. Somerville (Dawbarn and Ward, 1s.), and "Toning Bromide Prints," by Blake-Smith (Liffe, 1s.). (5) Certainly, they are as permanent as the original bromide: that is the experience with them up to now if properly made.

**GLAZED POSTCARDS.**—Having a large quantity of the ordinary coloured postcards on hand which would sell quicker if glossy, is it possible to have them glossed? If so, kindly say where I could get them done?—POSTCARDS.

McCaw, Stevenson, and Orr, Belfast, undertake work of this kind, though whether they can do it in the case of your prints we cannot say. Better write them.

**DEVELOPING DISHES.**—Could you kindly give me the name of an enamel suitable for developing dishes?—GEO. REIDAS.

Aspinal's is the best we know of for the purpose. If the dishes are of metal two coats should be applied—the second after the first has become thoroughly dry.

**BUILDING ACTS.**—Is it possible in the London building area to erect

a portable studio—viz., a tenant's fixture in the garden—without the necessity of putting concrete and brick foundation, as is required to a permanent structure under the London Building Acts *i.e.*, similar to a portable greenhouse. If it is possible, can it be built of wood, or must it be of corrugated iron, and is it necessary to place the same on wheels? My garden is 30ft. long, and I am desirous of building a studio size 24ft. by 10ft., 8ft. at the eaves, which would be 6ft. from the house. Would I have to give notice to the district surveyor?—STUDIO.

We are rather inclined to doubt if you will be allowed to put up such a structure in the space at your disposal, as you propose. Suburban district councils have their own bye-laws as to buildings, which vary in different districts, and you had better get those applying to your district. Your best way will be to see the district surveyor of your district, and he will tell you what you may, and what you may not, do. No doubt you will have to submit plans to the council.

**COPIES NOT EQUAL TO PROOFS.**—Three weeks ago we sent an operator to photograph a cricket team. The photographs turned out very good, and we submitted proofs to the secretary, and he sends back and says they are very satisfactory, and gives us an order for twenty copies. His brother calls and fetches fifteen copies and pays for them. Next day the secretary sends them back with the complaint that they are not good, and that they look like the work of an amateur, and that he wants fresh copies.—F. B. S. AND SONS.

Apparently the copies are not so good as the proofs you submitted. Therefore, it is not surprising that they are returned for replacement. One would have thought you would have made no demur to that for the sake of the credit to your business. People when they order duplicates naturally expect them to be equal to the proofs submitted in the first instance.

**W. H. W.**—Surely you are better able to assess the value of your own work than we can be who have not seen it. We should suggest that the charges be similar to those you make for your general outdoor work, whatever that may be, making the travelling expenses an extra charge.

**WIMBLEDON.**—Permission to photograph in Hyde Park, St. James' Park, and Hampton Court may be obtained from H.M. Board of Works, H. W. Primrose, Whitehall, S.W. For Windsor Park application should be made to Captain Walter Campbell, Holly Grove, Windsor Park.

**MARYPORT.**—If you will tell us the numbers in which the articles referred to appeared we shall be able to answer your queries.

**SPOTTY PAPER.**—Can you explain cause of spots on enclosed paper? It is an albumen paper, and I should be pleased to know cause and if there is any remedy.—JOHN RIDDEL.

You do not say if you purchase the paper ready sensitised or sensitise it yourself. So far as we can form an opinion from the pieces sent, the spots appear to be due to metallic particles in the paper, or the coating on its surface which has reduced the silver. Your best remedy is to return the paper to those who supplied you with it and get them to replace it.

**CECILY.**—"A Treatise on Photogravure," by Herbert Denison. (Liffie, 4s. 6d.)

**ADDRESS WANTED.**—I shall be much obliged if you will kindly let me know the address of a firm who supplies sheets of aluminium for making carbon prints on.—B. WALTERS.

The British Aluminium Company, Queen Victoria Street, E.C. **BUSINESS.**—About ten weeks ago a young lady came into my studio and ordered four coloured miniatures, 2 in. x 1½ in. (which we sell at 3s. 6d. each). A few days later she called again and got two of them, and was very pleased with same, but she did not inquire the price. The remaining two were forwarded by post about a week after, and we did not hear anything more about them. At the end of August I sent an invoice for 14s. Three days afterwards she wrote and returned two, saying they were not satisfactory (they were, however, exactly like the first two which she had kept), and that she had made arrangements with me to have four at 1s. each. Of course this was a falsehood, and I returned them along with a letter asking for immediate payment for the full amount. This she ignored, so at the end of September I threatened her with legal proceedings in the county court. Yesterday I got a letter as follows:—"Dear

Sir,—Your note to hand; I will gladly await events.—Y etc." What would you advise me to do with her? You she has kept all the four, and now absolutely refuses to pay them.—COUNTY COURT.

It appears that the order was given with a knowledge of price, and the lady is therefore liable for the amount.

**FOG FROM ALUMINIUM.**—1. I have three D.D. slides (half-plate) aluminium draw-out shutter. These constantly fog the paper. Can anything be done to prevent? I find it is where the catches which hold the plates scratch the shutter a line appears on each plate exactly opposite each catch. 2. Is any plain salted paper (sensitised) on the market now, or tised matt albumen? In looking over some old portrait I like them far better than those made on P.O.P.—WEEDE.

1. Aluminium when bright is very prone to fog the paper but not when its surface is dull or oxidised. The remedy your case is to bend the catches slightly so that they do not touch and scratch the metal. 2. So far as we are aware, there is none at the present time. Matt albumen paper may be had from most of the large dealers.

**ENLARGING.**—1. Is there any disadvantage in using a half-plate enlarging lantern, with 8½ condenser, for quarter-plate negatives? 2. Can a half-plate Aldis lens, f/6, 7½ in. equivalent focus, but about 6½ in. back focus, be used with half-plate enlarging lantern, 8½ in. condenser? I have seen it stated that a lens should be used which has a focal length equal to or rather less than the diameter of the condenser.—T. W.

1. If negative is placed close to condenser light is lost, and it is moved forward to a position where the diameter of the cone of light is only about 6 in. this defect is remedied. 2. This adjustment there should be no disadvantage. Enlarging from half-plate close to condenser then the focus is rather short, but still we have little doubt you can obtain good results if you adjust the light carefully. If enlarging from a quarter-plate placed in advance of condenser, as described in 1, the lens should be quite suitable. By adjusting space between condenser and negative, and also that between light condenser, you can get the best results from lenses of very focal lengths.

**INTENSIFYING AND REDUCING.**—1. When intensifying with bichloride of potash as a bleacher and hydroquinone-soda as a blancher an orange-coloured stain appears generally near edges of the negative. I send specimen. Will you say what is the cause? The stain only appears in some negatives, not in all, in the same position. 2. When reducing with ammonium persulphate some parts of the negative (generally the dark parts) assume a brown tint. Is this? STAIN.

1. This is probably the ordinary hydroquinone stain, produced either by applying developer before bleached image is printed, or by developing in too strong a light. If you use hydroquinone, wash well and develop in artificial light very diffused daylight. Amidol is much better, as it gives greater intensification and is less liable to stain. 2. This is due to developer stain in the image, which stain may be removed by dissolving away the silver. It may also be due to fixing after reduction. You can use sulphite or hypo for

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received by the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Exhibition of the Society of Colour Photographers closes at tomorrow week, Saturday, October 26.

Exhibition of examples of photographic portraiture by artificial pens at the house of the "B.J." on Friday, November 1.

Autochrome Portraits.—Some suggestions as to the display and practical utility of the Autochrome plate to the professional photographer appear on pages 782, 784, and 791.

Arthur Payne, F.R.P.S., gives the results of his experience making of stereoscopic "Autochromes." (P. 784.)

Martin Duncan, next Thursday, is to lecture at the Blenheim on "The Application of 'Autochrome' plates in Natural History," with lantern illustrations. (P. 798.)

A remarkable "experiments" in the Warner-Powrie process have been described. (P. 783.)

E. König sends us a formula for the home-preparation of orthochromatic plates requiring no light filter. (P. 786.)

A valuable hints on professional photographers' advertising communicated to the Professional Photographers' Association week by Mr. Edgar Scamell. (P. 787.)

Suggestions for the Christmas season appear, among other topics, "Wayside Notes." (P. 790.)

New cameras, a new view finder, and a camera case imitating a hand-bag, appear among patents of the week. (P. 792.)

There is every reason to anticipate a record meeting of the Photographic Convention next year at Brussels. (P. 782.)

Portraits from Likenesses.—The views of Mr. O. W. Beck on the question of an idealised portrait are contained in the first portion of recent paper. (P. 788.)

Snowden Ward on photographic picture making, and Mr. E. Scamell on flower photography, are reported under societies. (P. 791.)

"The advantage of being another's man's wife." (P. 800.)

## EX CATHEDRA.

### Autochromes and the Fixing-Bath.

Professor Namias has recently referred to a cause of weakening of the autochrome image in the fixing-bath, which, it may be remembered, was the subject of a word of caution from Mr. E. J. Wall in an article which appeared in the "Colour Supplement" of August 2. He points out that on the immersion of the plate after intensification in the permanganate solution H a deposit of brown peroxide of manganese may form on the film, and will lead, on the plate passing into the fixing bath, to loss of density of the silver image in these portions. The remedy, as Professor Namias points out, is to remove the deposit by means of a weak bath of oxalic acid before placing the plate in the hypo. The preventive, we would add, is to remove the intensifier from the film by washing before transferring the autochrome to the permanganate. Still another bath in the making of the autochrome transparency is to be avoided if possible.

\* \* \*

### Art and Colour Photography.

A very popular subject of discussion just now is the question whether the autochrome process, or any other colour process, will be of any use for pictorial purposes. Many profess strong convictions on one side or the other, though it should be fairly obvious that the question cannot possibly be answered yet. It has taken a good many years to find out the pictorial possibilities of photography in monochrome, and it will take a good many more to ascertain those of photography in colour. We have, however, frequently been asked a very curious question by photographers who have proved their ability in monochrome work. It is this: Can I control values, etc., in a colour print by any process in the same way that I can in a monochrome print? Such a question indicates that the querist does not quite understand why he does exercise control in monochrome work, nor why such control is so often necessary. As a matter of fact, however, it is mainly the absence of colour that renders methods of control necessary as regards values. There are no colour contrasts in a monochrome print, and to make up for them various compromises have to be effected. In fact, a monochrome photograph or painting is a compromise throughout, and can never be anything else. The exact imitation of nature, which has for long been the bugbear of the pictorialist, can never be effected in monochrome; a perfect colour process will, however, render it possible, and when that process is forthcoming it will be time to see what can be done with it. As Mr. Mummery suggested in his presidential address to the R.P.S., the invention of a perfect colour process on paper will force photographers to consider and study its pictorial possibilities, while the photographer's training will have to be modified. Judging from some

colour discords we have seen in the shape of autochromes the training question will be a very serious one, for it is evident that many photographers have a very small knowledge of colour.

### Autochrome Portraits.

The question has been raised as to what is to be done with autochrome portraits. However good the result may be, it cannot be hung on a wall or put in an album, and nobody wishes to see it used as a window decoration. Possibly the best solution of the difficulty is to take a tip from the old daguerreotypists. A really good portrait mounted in a well-designed case, specially suited for a transparency, would probably be greatly appreciated. It would be worth some little expenditure on the case, which might be somewhat on the lines of the daguerreotype case, but arranged to open both back and front. The back might have a hinged flap lined with white to serve as a reflector, while the front might be arranged to serve as a light screen or shield to cut off as much extraneous light as possible. We are certainly inclined to think that autochrome portraits, handsomely mounted in some such way as that suggested, would speedily become popular.

### The Pictorial Professional.

Mr. Mummery, in his presidential address, aptly suggested that in pictorial work professional photographers who devote the whole of their time to the practice and study of photography should lead the way. Though much is owing to the amateur yet it is the professional who should be the acknowledged leader in all matters photographic. In other professions the amateur is practically nowhere. The amateur architect is an absurdity, the amateur painter or sculptor negligible, and the amateur musician a nuisance, more or less. There are exceptions, but they only serve to prove the rule, for in the fine arts the cleverest amateur is far behind the skilled professional in knowledge, in skill, and in opportunities of practice. If things were all just as they should be in the photographic world the same rule should apply, but unfortunately it does not; at any rate not as fully as it should apply. At the present day we may, perhaps, say with truth that professionals do hold the lead in the matter of portraiture. Or rather that a few of them do. There are clever amateur portraitists who do very good work, better than the bulk of the professionals, but still the best professional work holds the lead. This was not always the case, perhaps, but the fact that it is so now shows that matters are improving to some extent. Pictorial work, however, as apart from portraiture, seems to be almost entirely in the

hands of amateurs, and this is not exactly a healthy situation. It must mean one of two things. Either the professionals are neglecting a branch of their profession that pictorial photography is not of much real importance in spite of all the fuss that is made about it. Which is the correct explanation? In the painting world there is of room for both professional portrait painters and professional landscape painters. Why should there not be the photographic world room for professional photographers and professional landscape photographers? The pictorial variety, of course, not the simple makers. We are afraid the true explanation is this—that outside the ranks of the elect and select the pictorial result is only looked upon as an apology for a picture, interesting sometimes, but not worth consideration. The professional pictorialist does not exist because the public does not want him. And, times, the public is very rational in its demands.

### The Exhibition of Colour Photographs.

Four examples of Lippmann interference colour photographs have now been sent to the exhibition of the Society of Colour Photographers, at 24, Wellington Street, London. The interest of the exhibit is greatly added to the fact that the results are seen to the best possible advantage in the special observing apparatus made by Zeiss and designed by Dr. Hans Lehmann, of Jena. The apparatus will be found described in the patent specification abstracted on page 414 of our issue for May 31. Reference should be made to this specification for description, but, briefly stated, the essential feature is that by the aid of mirrors the photograph is illuminated very nearly from the direction in which it is viewed so that the viewing lens is placed close to or in contact with the photograph so that it virtually takes the place of the prismatic cover glass commonly used.

### The Brussels Convention.

The arrangements for this meeting have already so far advanced that at the conference held in the Palais du Mont des Arts, Brussels on Monday, the 7th inst., the entire programme was practically outlined. Sir Cecil Hertslet (President) presided, and among those present were Mr. W. Vanderkinders (Secretary), Capt. A. Van Bever, M. Chas. Puttemans (Vice-Presidents), Messrs. V. Potter and W. H. Smith (Member of Council P.C.) and Mr. F. A. Bridge; and there is no doubt that the programme to be submitted to the Council on the 10th inst. is carried out, the 1908 meeting will be a record every way.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### SCREEN-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1908 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

### IMPORTANT NOTICE.

Our publishers ask us to inform agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

**Latest Warner-Powrie!!**

A contemporary has published an article dealing with some experiments with the Warner-Powrie plates which appears sufficiently remarkable to merit comment. The author takes the attitude of the practical man as opposed to the theorists without practical experience who have hitherto been publishing information and experiments on those plates. It is, therefore, exhilarating to learn he finds, to commence with, that, in use, the plates are five times as fast as the Autochrome plates. The Warner-Powrie line screen and the compensator together give a forty times screen, so that if we take the Lumière at 1 Watkins, which we have been assured is too low, the sensitiveness of the emulsion with which the Warner-Powrie plate is coated must be 1,200 Watkins, an amazing result. We believe that the plates which have hitherto been prepared have an emulsion speed of about 10 Watkins, giving a Watkins speed of 6, which, though considerably greater than that of the Lumière plate, only corresponds to the results of these experiments. The practical nature of the author, we should imagine, has no objection to theory, and especially to elementary mathematics, which causes him to state that the lines on the Warner-Powrie plate are 500 to the inch; in the plates at present available the lines are 620 to the inch, a somewhat considerable difference. Mr. Powrie has never made a line screen. The writer has printed the plates by simply putting them at one foot from burning magnesium without angling, and states that the results are satisfactory, but unless one could actually see those results and are them with results obtained by the correct shifting of the printing frames, one must be pardoned for being sceptical. We have found that if really good results are to be obtained, and the colours not degraded whites, it is absolutely necessary that the theoretical conditions should be accurately fulfilled, and indeed, that the blue lines are narrow is quite sufficient to cause an appreciable degradation of the tones produced by the angling method; it would seem that in future as it would be desirable to make the blue line as wide as possible the same width as the green and red lines without subdivision. The author, in continuing to state that Autochrome positives can be printed on an Autochrome complementary negative in the same way. Naturally they can, but all the colours are added with white. This can easily be seen on viewing the picture, and on examination under the microscope. The cause is plain, namely, that, owing to the irregular and direct diffusion, in a patch of pure red, for instance, and green grains will be found transparent where they should be completely opaque, thus greatly degrading the picture. Even our writer has noticed that the reds were subdued, though he ascribes it without the truest reason to an excess of ultra-violet in the magnesium flame. He also states that he has been fairly successful in the production of prints from Autochromes on paper without mirrors, a statement which is at variance with that published in our columns by Dr. Smith, the author of the Uto paper. Another experiment published in the production of continuous tone negatives on Autochrome plates, in the same way as the Warner-Powrie continuous tone negatives are printed, but using a red light-source without angling. Naturally, diffused rays of the starch grain can be obtained, and it is possible that this method might be practicable, though in view of the irregularity of distribution, and the varying degrees of the differently coloured starch grains, one would like some more careful experiments than this remarkable writer seems capable of.

**Photographing the Rising Sun.**

In this month's "Knowledge" there is an interesting photograph of the rising sun showing the manner in which refraction diminishes its apparent vertical diameter and converts the disc into an oval. Unfortunately, the rising sun is a very unfamiliar object. We believe there are people who have never seen it, and probably never will do so except as the result of some very untoward accident or prolonged function. Nevertheless, a set of photographs of the rising sun, taken in rapid succession, would be well worth securing, for the effects are not only very striking but sometimes very surprising. We are, perhaps, inviting innuendos as to preceding events, but on one occasion we saw what appeared to be two suns rising together—two suns joined like the upper and lower portions of a "cottage" loaf. The lower portion shrunk rapidly while the upper one swelled, the effect being as if the lower sun was drawn into and absorbed by the other. No camera was handy, but the scene was distinctly one to be photographed, not merely on account of the curious phenomenon, but on that of the magnificent play of light and shadow over the sea of mountain tops that extends eastward from Snowdon. Unfortunately one cannot be sure of one's sunrise. Mist so often obscures it that a clear view is rather rare, hence a photographer who wishes to record it must not only get up early but be prepared to do so again and again. In fact, we heard of one man who visited Snowdon every September for seven years just for the purpose of seeing the sun rise, and never saw it! He made one of his attempts the day before the one on which we were successful! Then also the photographer must be prepared for smart work and very rapid plate changing. Sunrise is a very brief performance. The sun literally jumps up out of the horizon, and one must have an accurately rated watch to consult, or the whole effect may be missed.

\* \* \*

**A Patent for Composite Negatives.**

In our "Patent News" column we recently published the specification of a patent for the production of "Backgrounds in Negatives," the patent being in the name of a resident in Vienna. The description of the invention reads thus: "This invention relates to improvements in the method of obtaining a composite negative whereby a suitable foreground or background or both can be combined with a central figure or figures, and consists in photographing the principal object and the chosen background and foreground on separate plates or films, and in cutting out or removing portions of each negative film so obtained in order to build up a single composite negative. For this purpose it is necessary to employ plates or supports, the films of which can be readily removed or handled in order to transfer the cut-out portions to the final support." Then follows details as to how the work is to be done. Many of our readers, after they have read them, will no doubt wonder as to where this new (?) invention differs from the old methods of doing the same thing. Exactly similar methods are often used by wet-plate workers, and the formation of just such a composite negative was demonstrated at the R.P.S. last session. No doubt the examiners at the Patent Office have examined this specification, and find it has not been the subject of any prior patent, and hence it will probably be passed, and the patent sealed. This serves to illustrate what we said in the recent article on "The New Patents and Designs Act," namely, that would-be photographic patentees should make investigations for themselves as to what had been done before, and not rely entirely on the Patent Office investigations. One thing is a mystery in reading this specification and others of similar type—and that is the method by which the patentee

expects to reap a profit from his invention: only, so it seems to us, in granting licences to work the process. But when the details are fully described, as they must be in all specifications, any one can work to them, and then how is the inventor to know if the results are produced by the patented method or not? This is a question that does not seem to occur to many who take out patents similar to the above.

#### AUTOCHROME PLATES AND THE PROFESSIONAL PHOTOGRAPHER.

THE different processes of producing photographs in colours by the three-colour methods have been prominently before the photographic world for some few years past. But, except in the photo-mechanical processes, little has been done with them by professional photographers. It is true that some few—very few—have made a slight feature of them, but, unfortunately, with very little commercial success. Now that we have the autochrome plates of Lumière and Co. on the market one may well speculate as to whether this process will be employed by professionals. In conversation with several lately they all expressed the opinion that it was not likely that it would be taken up by them in the near future, as the price of the plates would be prohibitive. But, after all, is the process so very costly as compared with the three-colour method of working? With that, three distinct negatives have to be taken, each suited to the other. Then to get the picture three prints have to be made one from each negative, and if either of the negatives turns out to be faulty another has to be made. Even if all the negatives are faultless, a faulty

print from any one of them must be re-made. All means considerable cost in time, labour, and material, whereas with the autochrome plates the picture is obtained at once in the camera. Recurring to the question of the present price of half-plate autochromes is thirty shillings a dozen. On referring to some very old prices in our possession we find daguerreotype plates quoted at the half-plate size, at from twenty-five to thirty shillings per dozen, that is, practically at the price of the Lumière autochrome plates. This was the price for the plates, which the photographer had to clean, polish, sensitise for himself, which operation required considerable skill and experience on the part of the worker to get good results. The autochrome plates, on the other hand, are supplied ready for exposure in the camera, and require no exceptional skill in the manipulation. In spite of the price of the plates many daguerreotypists made large fortunes. We have had it urged that the autochrome plates are not suited for portraiture as they are too slow. They are slow, it is true, as compared with ordinary gelatine plates, but they are about the same rapidity as wet collodion plates and much faster than those used in the old daguerreotype process. Neither of these processes was at one time, too slow for portraiture. Other objections have been heard raised against these new plates are that pictures can only be viewed by transmitted light, and cannot be printed from like ordinary every-day negatives. The same objections applied to daguerreotypes; they could only be seen at certain angles of light, and could only be repeated by copying in the camera. So it will be seen that the Lumière process is, in some respects, very analogous to the old daguerreotype process as regards its limitations.

## STEREOSCOPIC PHOTOGRAPHY WITH AUTOCHROME PLATES.

Two letters which I have recently received from correspondents in the neighbourhood of London have given me cause to consider the reason why the colour examples exhibited in London seem to differ from those obtained in the neighbourhood of Newcastle-on-Tyne. That there is some difference is beyond question, for both my friends have an advanced knowledge of photography to say the least of their ability, and one of them assures me that the results obtained upon Autochrome plates are very wonderful, but not suitable for use in the lantern because of their lack of transparency, while my other correspondent states that the few stereoscopic slides he has seen produced by this process are far from satisfactory. I think that this apparently common fault must be due to the slides being made too dense by unnecessary intensification. In no other way can I account for the discrepancy in our experiences, for in my hands the process has produced excellent lantern slides which look really satisfactory when exhibited upon the screen, and the stereoscopic slides that I have made have met with approval, and, in fact, considerable approbation, from those who have examined them. This was not idle flattery, because many of our local amateurs have ordered supplies of these plates with the object of obtaining similar results.

It has been my good fortune to examine many examples of this process by various workers, and I am satisfied that the most practical and useful method of using these plates is in the stereoscopic camera. There are several reasons for this opinion. In the first place it is impossible to control the photographic and colour rendering of the plate except by spoiling the result with over- or under-exposure, and in a very slight degree by

varying the amount of intensification which the plate receives. Then these transparencies must be examined in a proper viewing apparatus, unless they are used in the lantern, and what is more, is it suitable than a stereoscope? It is also possible, and, in fact, very easy, to use one of the pictures upon a stereoscopic transparency as a lantern slide if a suitable carrier be used, such as a slide mount, or it can easily be built up from sheets of cardboard. Therefore I consider it distinctly advantageous to make use of the stereoscopic camera to obtain photographs which not only reproduce the natural colour of the subject, but also show it in relief. The results obtained are unique, and make one quite dissatisfied with the monotony of an ordinary photograph.

#### Some Results.

Perhaps it may be as well if I describe some of the results which I have obtained, though I wish to disclaim any particular merit upon my part, for all the credit belongs to the manufacturers. One of my first exposures was made upon a half-plate autochrome in the interior of a greenhouse, and, of course, is full of gorgeous colouring, but what I considered to be the most beautiful part of the picture was the exquisite rendering of the wet stone floor, the old bricks, the hot-water pipes and woodwork. The texture of the floor was especially good, and the difference between the one or two dry patches of stone and the remaining wet portion was marvellous both in colour and in texture. A later example was a photograph of a bridge spanning a river, the banks of which are covered with trees; this photograph was taken upon a very dull day, the necessary exposure being fifteen minutes at  $f/22$ , and a wonderfully true result was obtained, for the picture when viewed in the stereoscope ex-

reproduces the scene, all the atmosphere and colouring is in evidence, while the transparency and texture of the water is rendered in a manner seldom, if ever, seen in an ordinary monochrome stereoscopic transparency. Another view taken in "an time garden" on a dull, misty day confirms the wonderful rendering of atmosphere which is obtained on these plates.

### The Rendering of Atmosphere.

It has always been the opinion of those who followed the process of colour photography that, though the results obtained by the tricolour three-plate process were very beautiful when objects more or less in one plane were photographed, it was practically impossible to produce a good landscape photograph giving a considerable stretch of country, and more especially in the presence of moisture separated the planes. On this point the Autochrome process distinctly scores, for it does reproduce a landscape with the same amount of atmosphere as was present when the view was taken. In fact, it is impossible to obtain, say, a sunlight effect upon a dull day, or vice versa, for the plate reproduces the picture exactly as it is seen upon the viewing screen, so long as the amount of contrast is within the range of the plate.

### The Process is So Simple.

Provided that the instructions are carefully adhered to, there is no reason why an excellent result should not be secured by one possessing a fair knowledge of photographic manipulation. I have carefully followed the instructions which have been published in the "British Journal," "Photography," and other publications, and I can honestly say that I have not met with any difficulties, not even in frilling, of which more anon. Before I intend to assume that the reader is conversant with working details of the process, which will be found in the numbers of this paper\*, and also with the ordinary stereoscopic photography, so that in this article I will only treat of the use of Autochrome plates. The Autochrome process possesses the advantages that one plate is used in an ordinary camera with a light-filter placed in front of the lens, as is usual in monochromatic photography. There is therefore no difficulty of registration, and the troublesome standing and balsaming of three films, used in the superimposed film processes, is avoided. The fact that only one picture is obtained with each exposure is to me an advantage, as it does away with the social question of providing our friends with prints. The speed of the process is also not to be despised, as a photograph may be taken in one hour, reckoning the time from the commencement of exposure to when the plate is set to dry. I can manipulate these plates in a green safe-light, to which I refer later on. It is a light which has not fogged the plates in my hands, and yet permits of the retention of sight in all degrees.

When about to cut some plates I carefully dust the cutting-board so as to remove any small splinters of glass that might scratch the film, and then lay a sheet of clean blotting-paper over the board. Removing a plate from the box, it is laid film-uppermost upon the cutting-board with one end in contact with the strip of wood, the cardboard cutting-shape is then carefully placed upon the plate with one edge also in contact with the strip of wood, and the edge of a penknife blade is run across the plate so as to divide the film. The plate is then turned round, being careful not to reverse the ends, and the glass is cut with the means of the diamond, using the wooden cutting-shape as a guide. The plate and blotting-paper are removed from the cutting-board in contact, and the glass is broken apart, the presence of the paper preventing the fingers marking the film. After the top side of the plate has been cleaned, it is placed in the dark box with the glass towards the shutter of the slide, a piece of

the black cardboard that is supplied with the plates is placed upon the film, and the slide is closed.

Probably this is the best place to mention that when the plate is divided in the middle, after it has been developed and dried it is still necessary to cut through the film before cutting the glass; and if two fine scratches are made upon the film at each outer side of the plate, and through the centre line, they will be found useful in transposing the prints when mounting the transparency.

### The Exposure.

The whole secret of obtaining successful results lies in the exposure; it must be exact, much more so than when using ordinary dry plates, for, unfortunately, Autochrome plates appear to be greatly deficient in "latitude." In fact, I find it difficult to obtain a really successful result when the subject possesses a wide range of contrast. It is easy to obtain white and black, but difficult to obtain subtle half-tones in light grey and at the same time obtain a good rendering of dark colours. One of the most difficult subjects I have met with was an orchid possessing several pinky-white petals and a centre of dark crimson. The first attempt was badly over-exposed, and the texture and half-tone on the whiter petals were entirely absent; upon repeating the experiment with a quarter of the exposure I found that this white texture and half-tone was still lost through over-exposure, but the darker centre of the flower appeared to suffer from under-exposure. This is caused by the fact that the high-lights "burn" right through the film, and are consequently lost when the negative is converted into a positive. It is a phenomenon that I have noticed many times, but is not strikingly apparent in a subject possessing a small proportion of high-lights. In an ideal result the plate should receive such an exposure that when it is normally developed only the highest lights should have penetrated right through the film. It seems to be that, contrary to the usual practice, it is necessary to expose for the high-lights and allow the shadows to take care of themselves. At this early stage there is not sufficient experience available to allow definite rules for exposure being formulated, but I may say that in landscape work I assume that the plate has a speed of 3 according to Watkins' meter, and this has given me successful results—better results, in fact, than when the exposure has been calculated according to a plate speed of Watkins 2. For indoor work, such as portraiture and still-life studies in the studio, I have obtained successful results when the plate has received an exposure of eight tints upon Watkins' meter with the lens working at  $f/22$ . I mean by this that the length of the exposure is the time that the paper takes to darken to the standard tint multiplied by eight, when the meter is held near the object and facing the source of light. I may mention that the meter must also be held facing the light in landscape photography, and not held in the shadow of the body. As I have already said, it is necessary to expose for the brighter portions of the subject and allow the shadows to take their chance. Under-exposure of the shadows appears to be preferable to gross over-exposure of the high-lights. I am unable at present to account for the discrepancy in the exposures when the plate is exposed in or out of doors.

### Halation.

The absence of halation in the results is not the least pleasurable quality that these plates possess. The photograph of the greenhouse to which I have already referred was taken in such a manner that it is possible to see the objects outside the greenhouse, and, though a prolonged exposure was given, there is absolutely no trace of halation upon the sash-bars of the windows. I have also observed the absence of halation when examining the several landscapes that stand to my credit—or discredit.

ARTHUR PAYNE, F.R.P.S.

## NON-SCREEN ORTHOCHROMATIC AND PANCHROMATIC PLATES BY BATHING.

[The following communication from Dr. König, of the Hoescht firm of Meister Lucius and Brüning, should be read with interest as supplying a ready means of preparing a highly orthochromatic plate by bathing those of the ordinary type. The procedure may frequently be of service when a screen for some special lens is not at hand.—Eds. "B.J."]

It is well known that in all orthochromatic and panchromatic plates the blue-sensitiveness peculiar to silver bromide is always much greater than that for the less refrangible rays produced by the colour-sensitiser, so that it is necessary to use a yellow filter during exposure to reduce the action of the blue rays. Since the use of the yellow screen is always somewhat inconvenient, many manufacturers have, during the last few years, placed on the market orthochromatic plates which contain the screening yellow dye in the film, and have thus enabled the user to dispense with the yellow screen during exposure. These plates

In this solution, which will keep indefinitely, the plates should be bathed for two or three minutes and dried without washing. The bath may be used over and over again, and only needs refreshing from time to time. The plates are always clean, free from streaks or spots, and will keep for three months unchanged.

I should not omit to mention it is not every plate that can be sensitised with erythrosin, and, unfortunately, I am not in a position to name any English plates that are suitable, though doubtless many are.

In developing some of the yellow dye remains in the developer.

Exposure of a colour chart taken without filter. The green is composed of blue and yellow, and appears very bright, in consequence of the blue in the plate used.  
A. Ordinary plate. B. Panchromatic plate with rapid filter yellow (pinacyanol and erythrosin). C. Orthochromatic plate, erythrosin only as sensitiser.

are not always satisfactory, and I have therefore endeavoured to find a method of making such plates by bathing ordinary plates. The results can be seen from the accompanying illustration.

There are not many yellow dyes which are suitable for this purpose, as there are several conditions to be fulfilled. The dye must be easily soluble in water, it must stain the gelatine, but must be easily washed out; it must not react with the sensitiser, nor be prejudicial to the keeping powers of the film. All these conditions are perfectly fulfilled by "filter yellow K," which is already well known in England.

To make the sensitiser, 5 gms. of filter yellow K and 0.1 gms. of erythrosin should be dissolved in 600 ccs. of distilled water, and 300 ccs. of alcohol added. Methylated spirit may be used.

Dr. HANS HARTING, who for some years past has occupied the post of optical and scientific director of the old-established optical firm of Voigtländer and Sohn, of Brunswick, has accepted a position in the Imperial German Patent Office. The honour is one which will, we hope, console the firm of Voigtländer for the loss of their distinguished director. During the time that he has been at Brun-

swick, Dr. Harting has advanced the interests of his firm by introducing the new types of lenses such as the Heliar and Dynar, both of which have attained the highest reputation among modern optical instruments for photography. For the past five years Dr. Harting has acted as "privatdozent" for scientific photography in the Brunswick technical high school.

whilst some in the fixing-bath. After a short washing the plate is quite free from stain. Neither the developer nor the fixing-bath is spoiled by the yellow dye. My attempts to make a panchromatic plate with pinachrome and "filter yellow K" were not satisfactory. The sensitiveness with pinachrome is strongly reduced by the yellow. On the other hand, I succeeded in making a bath with pinacyanol, panchromatising by adding to 300 ccs. of the above-named solution 2 ccs. of a 1:1,000 pinacyanol solution. Plates thus prepared show an extraordinary action in the yellow, orange, and red, only the green sensitiveness left something to be desired.

The sensitiveness of the plates, sensitised with erythrosin, to daylight is about 0.4 times less than the sensitiveness of unbatched plates.

Dr. E. König

# ADVERTISING IN PROFESSIONAL PHOTOGRAPHY.

A Paper read before the Professional Photographers' Association by Edgar Scamell.

PRESIDENT AND GENTLEMEN,—

Upon starting a business, the first thing a photographer has to do is to consider the position and appearance of the premises which he is to carry it on, and their accessibility to the greatest number of possible customers. Prominence of position in itself a most valuable advertisement, a fact which is taken advantage of by such varying classes as church authorities, stores, and publicans, all of whom choose, if possible, a conspicuous corner site in a busy quarter, entirely for the value the advertisement, despite the fact that, at least in the case of the church, this position must in some ways be most undesirable; for instance, the noise of the passing traffic, which is such that one church I know of hangs out a large notice during winter time: "Please drive quietly."

Now, one question a man taking a corner or prominent site has to consider is whether the increased rental will bring a correspondingly large return in business, or whether the saving rent in less prominent premises could be made by other means of advertising to yield a better return. In considering premises, even two photographers, A and B, who turn out work of equal quality, other circumstances being equal, he who has the biggest show will secure the most orders. Thus, if A has a good shop-front but a poor reception-room, etc., and B has only a bow-way entrance but a fine reception-room, etc., of the two shop-fronts will secure the more customers.

The word "advertising" usually suggests "printing ink." The question is how to reach the largest number with the smallest outlay. Newspaper advertising is of no use if entered on in a hap-hazard way. Newspaper advertising is an art in itself. Naturally, of course, one will choose the paper with the greatest local circulation. If the advertisement is to appear in an issue of the paper a change of wording should be frequently made. An advertisement appealing to the devotees of cricket and tennis should not run into the football season, or a reminder of enlargements make acceptable Christmas presents appear throughout January and February. On signing a contract for a man's advertising in a local paper a set of twelve suitable words might be written out with instructions to change the wording with each month. Probably the best newspaper advertisement is to secure insertion of little paragraphs amongst the body news. An insidious advertisement can often be arranged if one happens to know the right man on the staff of the paper and make it worth his while. A paragraph of this nature:—"At the opening meet of the Broomfield hounds Mr. A. Darkslyde made a very successful series of pictures of the field, including a portrait of the new Master, Lord Bremmer, mounted on his famous grey. The pictures are on view at the studio in Westgate Street."—is worth much more than the same space in the advertising columns. A friendly reporter at a wedding or other event will often, if suggested to him, note in his report the fact that Mr. A. Darkslyde was professionally present: and the advertisement is good, legitimate, and, as a rule, inexpensive. Judge by the advertisements of large commercial firms, it pays better to have one large space occasionally than a small one regularly. Drapers, for instance, take a whole page for a sale or something special, and only then. In newspaper advertising a difficulty is to trace a direct result. Those selling goods through the post often adopt the plan of intimating that orders are to be addressed "Department A, B, or C," as the case may be, each letter indicating the newspaper in which the advertisement appeared; but this system can hardly be applied to the photographic business.

Having once advertised, the photographer will be visited by agents and conditions of canvassers for advertisements. Pro-

motors of bazaars will offer pages of their handbook; the editor of the church magazine with its limited circulation; the local estate agent who wants to print a list of properties to let—with someone else to pay for the printing—and many others will call and waste time; and they are only to be encouraged when the photographer can clearly see that it is a matter of policy to entertain their offer on account of the orders he will indirectly receive, regardless of the actual advertisement, which usually is nil. One of the most efficient ways of employing printer's ink is for the photographer to run an advertisement of his own in the form of a good booklet delivered by post to carefully selected addresses. This will take up a considerable amount of time, but the result is generally satisfactory if the matter is well managed. The booklet appeals directly to the reader. It conveys precisely the information the photographer wishes to convey, and, being complete in itself, it avoids the possibility of being overlooked by being swamped in a multitude of other advertisements. The trouble is the proper distribution, but, this properly done, nearly every copy reaches the actual person for whom it was intended. If the booklet is artistic and attractive, there is a distinct possibility of its avoiding sudden death in the waste-paper basket, and if it is kept there is a probability of others besides the recipient seeing it.

Each picture sent out by a photographer is an advertisement in itself, and it must be remembered failures are more likely to be talked about than successes. It is taking a low estimate to say that it takes three good pictures to counteract the harmful influence of one bad one.

There are about half a dozen well-known photographers in London who are content with nothing more than a brass plate on the front door, but the majority show specimens in some way or other. Our good friend the Editor of the "British Journal" at frequent intervals tries to impress upon photographers the necessity of keeping show-cases fresh and clean and filled with seasonable pictures. In his opinion and my own constant change is one of the best advertisements. A small show changed frequently will give a better return than a large one changed, say, once a year. An American photographer reduced this to the extreme point by showing only one picture on his door-post, but that one was changed every morning. The same principle applies to show-cases at railway stations. A superintendent of advertisements on one of the railways with about fifty railway stations under his inspection cited, as an example of the carelessness of advertisers, a photographer who had a show-case on an important station. The show-case had remained for months with a broken glass and the prints ragged and weather-stained. Thus the photographer was paying rent for a directly detrimental advertisement of his work and business methods. If this photographer's system had included changing the contents of the show-case once a month, say, such a state of things would have been impossible. Advertisement contractors have no compunction about shifting a show-case from a conspicuous position into any obscure corner, and have been known to take a case down and stow it away entirely. A periodical visit for the purpose of changing the specimens would keep a check upon such doings. The object of a show-case or a window display, or whatever it may be, is to attract attention and create interest. If it does so it brings customers. If, on the other hand, the passers-by can find nothing to interest them it serves no purpose that a sign-board would not answer as well, if not better.

Advertisement is not necessarily of a direct nature. The doctor or dentist who desires to establish a practice joins the local debating societies, tennis and golf clubs, gets on to the committee of the flower show, and manages to be personally

in evidence at as many social functions as possible; and, similarly, solicitors, surveyors, architects, and other professional men take means to bring themselves into contact with their fellow-townsmen who are able to do business with them and put business in their way. The portrait painter must of necessity mix a good deal in society if he wishes to succeed.

It is well to study the methods of advertising adopted in other professions, and to consider whether these methods can be applied with advantage to photography. The best advertisement for a professional man is the man himself, and those who wish to adopt this method of advertisement must avoid that aloofness that is so frequently the characteristic of the professional photographer, must mix with their neighbours and fellow-townsmen, must interest themselves in local matters and take part in the social functions of the town, and, in becoming known personally, their businesses will also become known; but while doing this missionary work, do not forget that the work at home must be going on with regularity both in quality and promptitude.

In reference to advertising the man himself, one of our members from the country once called on me at the time of our borough council elections. Now, just opposite my premises there was a hoarding displaying many election posters. Our member greeted me with: "How are you? Why isn't your name up opposite?" I said I didn't take any interest in such matters. "That doesn't matter," said he; "you ought to come out as a candidate every time. You don't even want to be elected, but people will say when they see a fresh name up: 'Oh! who's Darkslyde, who's put up against Smith for the Broadway Ward?' The reply will be: 'Oh, he's the photographer in the High Street; don't you know his place?' etc., etc." A very good advertisement, although an indirect one, and to be obtained at quite a reasonable cost. A business man who rose from small beginnings to the position of mayor of his town told me that during the process he and his customers gradually changed places. In the beginning they dictated their orders and wants to him, and he had to carry out their wishes; but in the end they came asking his advice as a man of experience, and he dictated what they ought to have.

Directory canvassers are often sharks of whom we ought to beware, but a small advertisement in the right directory may not be money badly spent.

We have now considered the "How and Where" to advertise;

let us turn to the "When." Canvassers will tell us that we are slack is the right time to advertise, and the more general the depression so much the greater need. This is only partially correct. In a London suburb what would be the good of making a big advertising effort during August and September, everybody is away? We can see that the large users of positions on the hoardings study this point. Firms selling soups, beef extracts, with the approach of winter, are now occupying the spaces vacated by the summer advertisements of the li juice and lemonade makers.

Consider whether you wish to do a business with a small turnover and a large percentage of profit, or a large turnover with a small percentage of profit. In the latter case it is necessary to be in touch and reach of a very large number of people. Is your town or neighbourhood large enough not to be worked dry in the course of a year or so? My own ideal would be to occupy centrally situated premises of moderate dimensions, with space for a moderate show frequently changed.

In seeking for work to be done, I should endeavour to get into practice most of the schemes I have here touched upon, feeling convinced that the majority, if carried out in the right way, could be made to pay, according to the neighbourhood selected.

Remember that customers cannot come to you if they have never heard of you. Most people's memories are short, and customers who have been to you once will want reminding of your continued existence. What would become of Pears' soap if the advertisements were discontinued? Beware of all advertisements where you are given so many copies and have to trouble of distribution yourself. The distribution is always a serious question, and must be well done. A good business man who is only a moderately good photographer will make more money than a first-rate photographer who is only a moderately good business man. To the photographer in a small way would add: Don't do too much dark-room and routine work yourself; your assistants can be taught to do that, and your time can be better employed. I will conclude by quoting from a little booklet, a copy of which I believe each of us has recently received:—

"In advertising, nothing is cheap that doesn't make money, and nothing is dear that does." But would add to it an appendix that in advertising let us all consider our dignity and dignity of our profession.

EDGAR SCAMELL

## PORTRAITS FROM LIKENESSES.

[The following paper, read before the recent American Association of Photographers, is by Mr. Otto Walter Beck, whose book, "Pictorial Principles of Portrait Photography," reviewed in our pages last week, is now obtainable in this country.—Eds. "B.J."]

ALTHOUGH perhaps unaware of it, workers in photography are gradually being drawn closer to the great educational system of our country. The union will be effected as soon as the principles that underlie pictorial art are more generally understood.

At what point have we arrived in relation to this? In photography we have found out what is the difference between the copying process and that which really constitutes pictorial photo-portraiture, while in the schools the pictorial principle is being disengaged from principles that govern decoration. We believe that a service has been rendered to photography by the formulation of art principles that clearly state the differences between the subjects mentioned. We now know what art in photography is, and can work at its problems, thinking clearly and logically. We are on the right path. The public will be educated to an appreciation of art by our work, and its influence will reach far into the systems of the schools, public and private, at home and abroad. There exists at present no system that so

effectively reveals the secrets of pictorial construction as the evolution of our photography has evolved, and no mental training can exceed in value that offered by the analysis of a photograph having pictorial balance. It is well suited to the capacity of our scientifically inclined American in the studio or the college.

Does not a new light come to us when, looking ahead, we see art in photography working smoothly as a system in the great educational machinery of the world?

We are facing an incoming tide of new ideas. I say to men who advocate good, straight photography, go on with it; it is as sound and safe as photography, but he who places his sole reliance upon straight photography will remain upon a level with the copyists in painting. It is my conviction that good, straight photography will always be the base, but that treatment of the plate is necessary. To bring mind and soul into the work must create. But you will say, "We do all that is possible under the skylight; we are careful in selecting the pose, the

take great pains with the lighting, and finally we choose the most suitable among the backgrounds—either the plain, graded, or ornamental effect." And I ask in turn, "Is that enough?" For we test whether the truth of the camera is a picture truth. Assuming an everyday experience, someone enters our studio for the purpose of having his portrait made. While conversing with our eyes seek his gaze, and in his eyes we read his thought, form acquaintance with his disposition, his character. Through the eye's communication we form the friendship that is to be perpetuated in our portrait of him, for the portrait must always express that kindness, neatness, and approachableness that affect us as pleasing in life. We also observe his mobile features and the peculiarities of his figure, and our mind reads with emphasis the characteristics to which we were impressionable. As for the rest, we have less distinct memories. When we represent this man graphically it is natural that what most impressed us shall be recorded with due prominence; that minor observations shall be treated with breadth; that is, with an absence or control of disturbing detail. After that we call to our aid our art-training, to make sure that the background and further treatment shall help the impression we have succeeded in recording. In fact, this treatment of the background is the poet's touch, giving to our portrait those qualities that enhance the beauty, invigorate the personality, and make the whole representation satisfactory to our most fastidious tastes.

What does straight photography do with this same subject? The camera fails to reproduce the person as he appeared to us. It records a maze of detail, all over facts, as passionlessly and unintelligently as does a mirror. Because of this we have no assured start, no emotional outflow. Instead, the mind reads soberly the disjointed records.

Notice in a good picture how you are not allowed to escape; how skillfully the artist has made you look back, always back, that he wants you to see. On the other hand, a straight photograph leaks in all directions; its strength is not garnered. This being true, then behind picture-making there must be laws that we are to observe quite as carefully as we obey laws in chemistry. But in straight photography there is the belief that we have but to follow the formulae for posing, lighting, and even backgrounds to make a portrait. Let us see whether we can not change our views in regard to them. I will analyse the first: In the pose you seek to bring about naturalness. What is your whole aim, is it not? Unless, indeed, you elect to make the fantastic, or seek what you call "style," which is artificial, and a great strain upon sincere art. But I must point out to you that although naturalness is good to observe, its rendering depends upon something more than photographing a natural pose. It depends upon a treatment of the abstract obtained in the appearance, to render the natural, to portray character, to infuse "mood," and insure all those finer qualities that the portrait must have. This is the most important principle that underlies portrait work. If we can once gain this insight of view our progress towards mastery in art will be rapid. Those writers who have recently criticised our art-educational work could not penetrate to this great truth they would not try to stem a tide that is irresistible, for art-education will surely place opinion by fundamental truth.

I ask you to observe this pose of a man clothed in dark, and standing against a dark ground. What kind of a picture shall we make of him? Shall it be a poster, a snapshot, or a portrait? Looking at the poster, we so treat the representation that the line and the mass of the body become the notes of importance, the head being of no more interest than any other section, whether body or background. In making a poster we follow certain laws that are absolutely and completely at variance with portraiture. In the poster we aim to destroy the sense of "body" and of personality, in order that other factors may lead.

If we want the snapshot we focus on the man somewhere, and there is presented to us in the print a monotonous recounting of detail, with no interest above the superficial.

To attain to portraiture our camera must be used with particular intelligence. We must first conceive the portrait in the pose, and secondly, we must develop the picture in conformity with this conception. Boots do not enter much into our notice, nor do details of dress or texture of cloth, when we are intent upon the personality of an individual, but the snapshot does take notice of them, and even with your best efforts to avoid it, good straight photography records them too prominently. We therefore have to learn how to repress the unimportant, that we may give prominence to the sitter's striking features, whether mental or physical.

Being luminous, the flesh is a chief pictorial factor. Therefore the face and hands are to be especially considered, and we must make the utmost use of them, giving them prominence and subduing all else. Our eyes must be made to glide over all minor matter to the point having the portrait interest.

To illustrate, this man assumes a pose standing squarely facing us, his hands being dropped to his sides. The art laws dictate that we shall so represent him that our eye will especially note his face. In this pose, however, the geometric placing of hands, head, and feet makes the face only incidental and brings into strong evidence the centre line of his coat, with buttons. Therefore, the portrait is impossible with this arrangement, unless we are resourceful enough to make the background help us out of the difficulty.

When we change the pose, permitting one hand still to hang at the side while the other holds a scroll against the chest, we force the observer to follow these light spots in their order, the gaze resting finally upon the face, where it will be held. In this pose we have a good portrait opportunity, but there is a possibility that we shall lose it in the further treatment. I will speak of this presently.

Suppose we attempt to lay into this man's portrait a loftiness that we felt to be inherent in his character. How often you have met this problem. Have you been able to solve it? Is it not true that when confronted with the task of making a portrait of the unusual man, the man prominent in one of the callings of life, you have exhausted your ingenuity in using the pose, lighting, and the ready-made backgrounds in your effort to make him different from the weaker type of man? What would you not give to be able to bring out the life, the dignity, the power of such a man? Yet how simple are the laws that lead to an expression of these coveted qualities. We have but to guide the observer's eye to the floor line. I do this by placing a large white piece of paper behind and at one side of his feet. This white spot is an accent, drawing the observer's gaze to itself, and from this point the eye climbs the figure to the first hand, across to the second, and then sways to the last and final point of interest, the face. Does the man not seem taller, possessed of increased dignity and firmness? Yet the pose has not been changed, nor shall we alter it now, while producing an effect differing greatly from this one. Our aim shall now be to make the man appear shorter in stature. I place the paper previously used at his feet, behind and to one side of his head. Immediately your eyes seek his face, because it is powerfully reinforced in accent. You see the face so intently that it appears to come forward, and the man's expression assumes an eagerness and intimacy. He is now the "hail fellow well met," who meets you more than half-way, who does not stand on formality. This, of course, is the quality that is often desirable in portraits, but it is disastrous to introduce it when our minds are intent upon the embodiment of some essentially different trait.

But we feel that we can hardly give a complete expression of "intimacy" by the use of the full-length portrait. Have you

not noticed that while your eye was drawn to the face you overlooked the lower part of the body? Because of this, the man's standing is not firm; he seems physically weaker. If you want to remove such defects make a half-length picture, and thereby get rid of the disturbing section. In the half-length

you can give as much weight to the "intimate" qualities as like; in fact, you may give full sway to your powers and into this more limited space such concentration, such technical handling as will ensure a most brilliant result.

(To be continued.)

## WAYSIDE NOTES.

I HAVE not had the pleasure of meeting Miss E. E. Barrett, the writer of the article on "Reception-room Routine" in "B.J." for September 6, but I feel no hesitation in saying that the photographer whose reception-room she is managing is a successful one. Her description of her day's work shows that she is capable, competent, a veritable model for every young lady who has just completed her apprenticeship and who is making her first essay as a fully fledged receptionist. But, you may say, her qualifications, be they what they may, do not necessarily imply that her employer is successful. My reply is that the best part of a photographer's business is done in the reception-room. If the operator in the studio is not "making good" with his negatives, if sitters are disappointed with their proofs, then that photographer will not long be able to pay Miss Barrett the salary she is worth; and, depend upon it, one who so evidently knows how to sell photographs will know quite well how to value her own qualifications.

A noticeable feature in Miss Barrett's description is the enthusiasm she feels in her work. She says her daily round is an exceedingly interesting one. Many another would term it worrying, tiresome. Strangely enough, the article appears facing the advertisement of a firm of trade enlargers who quote Goethe's dictum that it is liking what we have to do that makes life blessed, and who say that they are never so happy as when they are bettering their work. On the face of it, this statement appears absurd; but when one looks around, one sees that the majority of the successful workers in any vocation are those who really enjoy their work.

Writ large on the cover of a book on a railway bookstall I have just noticed the title "Get on or get out." I do not know what the book is about, but it might well apply to the choice of one's occupation. A man with any force of character who finds that he has started in the world in the wrong business generally manages to exchange it for a more congenial one. George Alexander and Rufus Isaacs both began in the City; Thomas Hardy, the Wessex novelist, was an architect; W. W. Jacobs, the humorist, was a Civil Service clerk in the Savings Bank Department.

The name of Furley Lewis is, of course, known to nearly every reader of the "B.J."; not so many, however, will know that his photographs are always distinguished by an embossed device—that of the fleur-de-lis. Talking with a photographer lately, I was asked where he could obtain a stamp of "the Prince of Wales's feathers arrangement," as he thought that it improved the appearance of the mount. I explained to him that I did not think that Mr. Lewis could have any legal property in the symbol, but inasmuch as, without any great verbal contortion, it was a very fair pun on his name, it was therefore not one that would have any particular value when used by anyone else. Walter Crane, the artist (a photograph of whom by Furley Lewis is in the present Salon), uses as his device a representation of the bird whose name he bears; and there are many photographers who could originate similar devices derived from their own names.

There have not been many days this summer when the has been in any degree oppressive, but there have been times when the suggestion of coolness that is always afforded by plants and flowers would have been welcome. Yet in a few reception-rooms does one ever see any relief of this nature. Either the growing plants in suitable tubs or pots, or else cut flowers in clear glass holders, form an agreeable contrast to the endless arrays of photographs generally seen. Of course they must not be the artificial variety—the rose tree, etc.—the photographic goods dealer. They are abominations to only add to the dry, frowsy appearance that all too easily is apt to pervade the reception-room.

Christmas, to the average man, is some distance from us, he who is gifted with the admirable quality of foresight already laying his plans. The majority of us get all our work we want in the fortnight or so immediately preceding the holiday; the great desideratum is to start the busy period earlier. Now, the public will always delay as long as ever possibly can—hence even they who have intended to be photographed for Christmas give their sitting just about ten days before they actually want to send out the photographs. The Suffolk saying runs, "They drive it to the last moment." Seeing that this is so, it behoves the photographer to come in as far as possible.

The first thing to do is to prepare a list of all the customers with the card index system as used by Mr. Pirie Macdonald. The list is always in readiness. A letter is then drafted to the effect that doubtless they will be wanting some photographs for Christmas, and that in order to give one's customary care and attention to the work it is desirable that the additional copies may be ordered, or the new sitting given, as early as is convenient. If the names are few, these letters may be written by the receptionist in her leisure moments; if there are many to be done in this way, they should be given to a printer to print them in imitation typewriter style. Whichever way they are done, be sure that they have the character of personal letters—not circulars. A good printer can now supply facsimile typewritten letters which only an expert can distinguish from originals.

If no reply be obtained a "follow-up" letter should be sent a week later; it can be made interesting by the suggestion of the desirability of miniatures or enlarged photographs for Christmas presents. In larger towns a tasteful folder may be substituted; it must be really good, though, because the photographer who is conducting an artistic business is on a different plane to "the butcher, the baker, the candlestick-maker," and should, therefore, when he does use advertising matter, see that it adequately represents his own artistic standards.

The approaching season is the best one in the year in which to run a special line. An admirable article appeared in the "B.J." some weeks back, describing the methods whereby Mr. Corke obtains his negatives of "fireside" effects by means of ordinary daylight. Two or three such photographs—a chi-

making toast, a girl reading, and so on—in, say, 12 by 10 size, properly stained and suitably framed, would prove very attractive, and should get many orders. It is on lines like these that the really skilful man can show that his is altogether a different business to that of the shilling-a-dozen concern.

\* \* \*

I know a man near Manchester who has a good-priced picture that he calls the "Marcus Stone." He has painted a background and has had made for him a stone seat, both in the style so well known to the middle classes by the many reproductions of the pictures of Marcus Stone. A great deal of the success of this picture depends on the ability to obtain a sitter sufficiently tall and graceful to carry out the idea of the A.R.A.'s pictures, as a specimen; if squat and dumpy females wish to be photographed in the same style—and nineteen people out of twenty seem to fancy that they would look best in a pose altogether unsuited to them—it is rather hard on Mr. Stone. He has, though, some little consolation in the proverbial "sincerest flattery." Another idea, one that is more easily carried out, and one, also, that is more likely to be popular, is that of the snow scene. A background, preferably with continuous foreground, of an exterior representing a scene with a heavy fall of snow, is within the capabilities of most background painters. A little toboggan for the juvenile sitters is a useful accessory. On the negative it is an easy matter to work in the appearance of falling snow. The man who has enterprise enough to run this idea, and also that of Mr. Corke's delight pictures, ought to make a good thing of them.

\* \* \*

The much-talked-of Autochrome plate of M.M. Lumière being by this time obtainable everywhere, here is an idea for getting some cheap publicity. Obtain a packet of the plates, carefully read the instructions, and make some transparencies of some well-known scene in your town. Choose one, of course, that shows some fairly vivid colouring in it. Then call on the editor of your local newspaper, show him what a notable advance has been made in colour photography, and tell him that you are showing the transparencies in your window. The chances are that he will accept it as a good news item—by which you profit accordingly.

\* \* \*

Thus reads the "Foreword" to the Salon catalogue: "TO OUR CRITICS.—Some critics will persist in thinking, and saying, that some methods of art are right and others are wrong. It seems only too easy for the partisan critic to be blind to the merits of a thing well done in a way of which he disapproves, and blind also to the defects of a thing ill done in the way of which he approves."

\* \* \*

Now, I don't care the proverbial tinker's cuss how a thing comes to me, so long as when it does arrive it pleases. What worried me at the Salon after reading the above waspy little foreword was to discover its application to No. 40, "Under the Chestnuts," and No. 59, "Snow Shadows." On a chair in the middle of the room—economical folk those Links; the thinking in which the furniture comes to the room they use for decorating their walls!—I espied some slips of paper. I made a rush for them, quite expecting that they were errata slips for pasting in the catalogue, and that on one there would be a note, "No. 40.—As Artemus Ward says, 'This is a goak.'" The man who knows Mr. Marshall's work can think of no other explanation. But no; they were not errata slips. They were little advertisements of four fourpenny handbooks for beginners. Other unkind, wasn't it?

\* \* \*

An awfully pretty girl was leading round the room a literary-looking old man, who was doing his very best not to look bored. He *did* seem interested in the furniture packing, thought; and then they came to something that evidently

attracted her immensely. "Oh, father, doesn't this look like a pastel; and, of course, it's only a photograph." His reply seemed directed more to the packing than the lady. From what I could hear, it seemed to run:—

"But the Devil whoops, as he whooped of old:

'It's clever, but is it art?'"

It was either that, or:—

"When the Devil mutters behind the leaves:

'It's pretty, but is it art?'"

THE MAN ON THE ROAD.

## Exhibitions.

### THE BRISTOL PHOTOGRAPHIC CLUB'S EXHIBITION.

THIS, the second annual exhibition of the club, was held in the fine suite of rooms of the Bristol Fine Arts Academy. The club had been fortunate in getting the guidance and active assistance of Mr. A. L. Coburn in the hanging and decoration of their exhibition, and at his instance the walls were first covered with brown paper of suitable tone and then agreeably panelled out by the free use of broad tape, dyed to a dark brown, the result being entirely satisfactory.

This year the entered works had been subjected to a rigorous selection, only about one-half of those entered being hung, with the result that a high average of artistic merit was reached, and the good works were not spoilt by overcrowding.

The technical section, which was kept apart from the pictorial, also reached a high standard. In the Invitation Section Mr. Coburn had five characteristically daring pictures, taken in the neighbourhood of Bristol, which attracted much interest and comment. Mr. S. G. Kimber's views of church interiors are wonderful in their rendering of sunlight and shadow. Mr. Percy Lewis is worthily represented by three Italian scenes, full of atmosphere. Mr. E. Seymour showed eight examples of fruit and flowers, in which the rendering of texture was very fine; while F. Hollyer had two strong portraits.

In the Open Pictorial Class Mr. Evershed's eight prints in oil show much feeling for colour and texture, combined with a lively appreciation of pictorial effect, giving the same impression as a delicate water-colour drawing. Mr. Basil Schön was represented by "Dingy London" and "Where Once an Ancient City Stood," both noteworthy for atmosphere and composition. Herr R. Dührkoop's ten portraits are forcible, and at the same time delicate in the handling of the lights and shadows; but, good as they were, they hardly came up to his work shown last year.

Mr. H. M. Haines' "At the Piano" is very poetical in composition, while a flower study by Jos. Bell, in Leto pigment, is good.

Mr. G. Hale manages to infuse much personality into his two gum prints, entitled "A Hertford Lane" and "A Landscape," but one or two minor false lights have been worked in. Mr. Oscar Hardee's "Portrait Group" is one of the features of the exhibition. It represents two heads (mother and son), the modelling of which is splendid, as is also the rendering of the relative tone and texture of drapery, faces, and hair.

Mr. Harry Lindoe's "The Deserted Mill" was a perfectly charming little oil print of a landscape at eventide.

H. R. Harford exhibits a number of prints which well deserved careful consideration, and E. H. Hazell has several child studies, evincing a fine insight into child life.

In the Members' Section the inspiring influence of a local exhibition is very apparent, a decided advance being visible, much really good work being shown.

"Winter," by George Easonsmith, is a delightful little print in platinotype, while four gum prints by E. G. Watts displays great technical skill, combined with artistic perception, the skies being particularly well rendered.

W. Brush, W. H. Hawker, W. W. Smith, H. C. Leat, F. N. Nield, W. A. Rowland, and E. Beaven also deserve special mention.

In the Technical Section Dr. G. H. Rodman has a remarkable radiograph of molluscal shells, showing their internal structure by means of the X-rays.

Mr. Henry J. Comley, secretary of the Society of Colour Photo-

graphers, was represented by four still life prints in natural colours, which were well composed and skilfully executed.

"Chaffinches," by Geo. A. Booth, was a triumph, from both a technical and pictorial point of view.

In the Autochrome Section Mr. R. Child Bayley shows six excellent examples of the wonderful capabilities of the process, while Morris B. Fowler contributed six, and Geo. Easonsmith four examples, both of these latter being members of the club.

#### FORTHCOMING EXHIBITIONS.

- September 13 to October 26.—Photographic Salon. Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.
- September 19 to October 26.—Royal Photographic Society. Sec., J. McIntosh, New Gallery, 121, Regent Street, London, W.
- September 30 to October 25.—Society of Colour Photographers. Sec., Henry J. Comley, Surrey House, Stroud, Glos.
- October 16 to 19.—Rotherham Photographic Society. Entries close October 7. Sec., H. C. Hemingway, Tooker Road, Rotherham.
- October 17 to 26.—Edinburgh and Midlothian Industrial Exhibition (Photographic Section). Sec., A. T. Hutchinson, 15, Leith Street, Edinburgh.
- October 30 and 31.—Watford Camera Club. Sec., W. R. Gunton, 139, High Street, Watford, Herts.
- November 5 to 27.—West of England Industrial Exhibition (Photographic Section). Entries close October 5. Sec., A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.
- November 6 to 8.—Bedford Camera Club. Entries close October 31. Sec., P. C. Penny, 64, Harpur Street, Bedford.
- November 6 to 9.—Hackney Photographic Society. Sec., Walter Selfe, 70, Paragon Road, Hackney, London, N.E.
- November 12 to 16.—Rugby Photographic Society. Entries close October 29. Sec., R. H. Myers, 13, Bridget Street, Rugby.
- November 19 to 23.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 25 to 28.—Lancaster Photographic Society. Entries close November 16. Sec., Walter Gunson, Manesty, Scotforth Road, Lancaster.
- November 28 to December 4.—Southsea Photographic Society. Sec., Gilbert Wood, 10, Pelham Road, Southsea.
- December 5 to 7.—St. George Co-operative Society Camera Club. Entries close November 25. Sec., George Anderson, 77, Brae-side Street, Glasgow.
- December 5-7.—North London Photographic Society. Entries close November 30. Sec., C. H. Madden, 12, Dagmar Road, Stroud Green, London, N.
- December 11 to 14.—Hove Camera Club. Sec., Stanley Read, 12, Old Steine, Brighton.
- December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telier, 138, Glasgow Road, Wishaw, N.B.
- 1908.
- February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

A SCIENTIFIC EXHIBITION.—A novel and interesting exhibition is to be held at the Royal Horticultural Hall, Vincent Square, Westminster, London, S.W., from October 22 to 26 inclusive. The event is being organised in connection with "The Model Engineer," and will include a splendid collection of engineering models of all kinds—electrical, optical and scientific instruments, technical education apparatus, and lathes, tools and workshop appliances. Many of the models will be shown at work. Scientific lectures and demonstrations will be given each day, the subjects including colour-photography, sound waves, wireless telegraphy, gyroscopes, X-rays, radium, electric wedding, and other interesting items. High-class music and refreshments will be provided. The price of admission will be one shilling.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between September 30 to October 5.

**FILING CABINETS.**—No. 21,655. Improvements in cabinets for storing or filing microscopic slides, photographic plates, and the like. Percy Merwood Fowler, 27, Chancery Lane, London.

**CAMERAS.**—No. 21,669. Improvements in or connected with photographic cameras. Major William Carter and Edwin John Fletcher, Birkbeck Bank Chambers, Southampton Building, London.

**COLOUR PHOTOGRAPHY.**—No. 21,685. Improvements in colour photography and apparatus therefor. Edmund Basil Wedmore, 16, Clifton Road, Rugby.

**FILM SPOOLS, ETC.**—No. 21,692. Improvements in photographic film spools, film packs, film envelopes, or the like, and in light-excluding wrappers for the same. John Edward Thornton, 16, Wellington Road, Heaton Norris, Stockport.

**EXPOSURE DEVICE.**—No. 21,745. Mechanical device for simplifying and expediting the exposure of photographic paper and the like. Michael Edward Abbott, 29, Cleveland Mansions, Chapel Street, Brixton, London.

**PRINTING.**—No. 21,769. Improved printing method. Joseph Southam, Enderlie, Selborne Road, Worcester.

**COLOUR PLATES.**—No. 21,768. Improved method of making colour sensitive plates or screens for photographic purposes. Arthur Lewis Adams and William Watson, 24, Charing Cross Road, London.

**CELLULOID.**—No. 21,880. Improvements in the manufacture of celluloid or the like. Self-Developing Plate Company, Ltd., and Thomas Bolas, 7, Southampton Buildings, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SELF-DEVELOPING PLATES.**—No. 21,189. 1906. The invention relates to films arranged in a pack with tabs, as described in Patent Specification Nos. 11,033, 1906, and 11,346, 1906. It is now proposed to provide such films with chemicals in dry state for developing or fixing, these materials being applied direct to the film, to the separate backing paper, or to some part of the manipulating tab. John Edward Thornton, Altrincham, Cheshire.

**CAMERA CASINGS.**—No. 24,962. 1906. This invention relates to portable casings for photographic cameras. It comprises a U-shaped body of any desired shape, similar to a lady's bag. This body is provided inside with guides obtained by giving the interior a suitable shape or by securing ledges on the outside of the body. The photographic apparatus held by the guides is introduced into the casing from the top, and is held in its position by means of a spring provided with a projection. To one side the body is hinged or jointed a plate, provided on its outside with ornamentalations, the plate being held closed by means of a pivoted spring catch. The opposite open side of the body, filled by the casing, or outer side of the camera introduced, in such manner that the folding bottom of the camera lies against this open side of the body.

The method of using this device is as follows:—After opening the back hinged wall is raised and the light screen for the opaque disc secured to the apparatus also raised. The bottom of the camera is released, the object glass holder corresponding pulled out, and the camera is then in the position for focussing the picture and taking a photograph without it being necessary to remove the camera from the casing.

If the casing is to be used as a lady's bag, which is possible after the photographic camera has been removed, the front opening of the body which had been closed by the photographic camera introduced into it, is closed by a plate covered in the same way as the body. The hollow space thus produced and accessible from the top can then be used for carrying various articles, like an ordinary lady's bag. A. J. Boulton, for Certo Fabrik Photo

graphischer Apparate und Bedarfsartikel Gesellschaft Mit Beschränkter Haftung, of Grossschachwitz, Dresden, Germany. KITE CAMERA.—No. 6,783. 1907. The invention is to enable sharp photographic pictures to be obtained by means of photographic

Fig. 1.

apparatus carried by a kite, etc. A limited falling motion of the apparatus is utilised, the apparatus being disconnected from

Fig. 2.

the carrier by mechanical means controlled by the operator, and the exposure made during the fall, whereupon the latter is

Fig. 3.

checked. The sharpness of the pictures obtained by exposure made during the vertical drop of the photographic apparatus is not interfered with by the movement of the kite.

Apparatus suitable for carrying out this method in connection with kite photography is illustrated in Figs. 1 and 2 of the annexed drawing. In the construction of apparatus shown in Fig. 2 a rod extends into a tube *e*, in which it is supported by a helical spring *f*. The tube *e* is connected to the frame *g* of the kite, and to the lower end of the rod *d* is attached a cord *h*, suitably connected to the shutters of four photographic cameras not illustrated, arranged in the spherical case. A cord *i*, one end of which is retained on the ground when the kite ascends, the other end being attached to the top of the rod *d*, enables the latter to be jerked upwards to release it from the springs *b*, whereupon the casing with the camera drops until the cord *h* is tensioned, the shutters of the camera being by this means operated to make exposures. Robert Bachstein, 17, Dürerplatz; Dresden—A; and Balduin Emil Enge, 22, Kronprinzstrasse, Oberlössnitz, near Dresden.

VIEW FINDERS.—No. 2,356, 1907. The construction of the new view finder is based upon the spherical concave reflector as illustrated in Fig. 1. Such a reflector produces a very bright image which has, however, the defects of being distorted and reversed. This defect of reversal of the image is compensated for according to this invention by using a reflector having a particular arrange-

Fig. 1.

ment of curvatures instead of a spherical curve. In the new view finder or reflector the principal curves are oppositely described.

Referring to the drawings, and particularly to Fig. 2, *a*

Fig. 2.

denotes the body of the reflector, the reflecting surface of which is a surface of double curvature. This surface is produced by the movement of a segment of the circle *b* struck from the centre

$p$  around an axis  $P^1 P^2$ , the circle described by one end of such segment around the centre  $P^1$  being marked  $c$ .

Assuming that the curvatures represented by the circle  $b$  and hereinafter called "meridional-curves" are concave, the oppositely directed curves which will be hereinafter called "equatorial-curves" are convex. The equatorial segmental curves all have their centres upon the line passing through the centre  $P^1$ , for instance the curve of smallest radius forms part of the circle  $c$ , and the curve of largest radius is struck from the centre  $P^2$ .

The surface thus obtained is a regular saddle-surface if the principal curves are calculated to be about equal in their absolute values but to be of opposite character. A reflector of

Fig. 3.

such a kind has been found just as the above-mentioned spherical reflector to produce images distorted and contracted in their upper parts. Those parts of the reflector therefore producing the upper part of the image are of a lesser equatorial curvature, that is to say, the radius of curvature  $R^1$  extends beyond or is longer than the radius  $R$ , as is seen in Fig. 2. In this manner the distortion may be almost entirely corrected. A reflector in which the principal normal curves form parts of circles and which can therefore be easily made in practice, will be sufficient for most cases. For completely removing the distortion, the exact form of a suitable surface (saddle surface) can be easily determined in a graphic and analytic way, the principal curves normal being of opposite character.

Figure 3 shows a view finder made as hereinbefore described. The finder  $a$  is provided with a sight  $k$ , and on the reflecting face of the body  $a$  a cross or mark is made to the proper point-

Fig. 4.

ing or sighting of the camera. It is preferable to arrange the finder in such a manner that one or both of its parts can be folded flat in the same way as the known Newton view finder, thus at the same time protecting the sight  $k$ . All these embodiments of the invention, however, do not interfere with the principle thereof, the characteristic feature of which is a surface having curves oppositely described.

Naturally it is possible to make a lens, as shown in Fig. 4, one surface of which is the hereinbefore described saddle surface and which produces in connection with a plane reflector at about an angle of 45 degrees and arranged behind the lens, a view of the kind obtained in the previously described view finder. This form (Fig. 4) is also a modification based on the above mentioned principle, but is not, however, so satisfactory. In

conclusion it may be remarked that the finder does not produce a real image; the image reflected in the finder consists of two parts, namely a real image produced by the meridional concave curves and a virtual image produced by the equatorial convex curves. Therefore the focal lines produced by the meridional sections can be collected on a ground glass screen or the like. Rathenower Optische-Industrie-Anstalt, vorm Emile Busch, Rathenow, Germany.

### New Trade Names.

IMPERIAL N.F.—No. 295,494. Plates included in this class prepared for photographic purposes. The Imperial Dry Plate Company Ltd., Ashford Road, Cricklewood, London, N.W., manufacturers of photographic materials. August 13, 1907.

### New Apparatus, &c.

Full View Printing Frames. Made by Houghtons, Ltd., 88 and 90 High Holborn, London, W.C.

A new idea in printing frames is embodied in this introduction by Messrs. Houghtons. The negative is inserted in a rabbet in one end of the frame and beneath a weak spring at the other. The paper is clamped tightly in register with the negative by a screw adjustment.

one end of the negative, so that the whole of the print can be examined, saving only the narrow strip ( $\frac{1}{8}$  inch), by which the paper is tightly clipped. The back of the frame is therefore made with a hinge, and the frames can thus be made at a price which is greater than that of the ordinary pattern—namely, 6d. each,

quarter-plate size, 11d. in half-plate, and 1s. 10d. in whole-plate. One advantage that might be mentioned is that the negative being clamped in the frame cannot accidentally fall out and get scratched or broken.

The Ensign Lens. Supplied by Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

Messrs. Houghtons announce a special offer of the newly introduced "Ensign" anastigmat lens, either with or without the well-known "Koilos" shutter. Up to the end of the present month they are prepared to supply two series of these lenses, working at respectively  $f/5.8$  and  $f/7.7$ . A  $4\frac{1}{2}$ in. lens of the former series costs in aluminium mount and iris diaphragm £2 12s. 6d.; whilst complete with the "Koilos" shutter its price is £4 12s. 6d. The lens, it should be mentioned, is separable into two components of  $7\frac{1}{2}$ in. and  $8\frac{3}{4}$ in., the other two numbers, Series I., being similarly divisible into lenses of about  $1\frac{1}{2}$  and nearly double the focal length of the complete objec-

ve. The Series II., at the lesser aperture of  $f/7.7$ , costs, in the case of the  $4\frac{1}{2}$ in. lens, in aluminium mount, £1 17s. 6d. A "Sanderson" camera, offering, as our readers know, a very great rise of front, gave a convenient opportunity of testing the behaviour of these lenses in actual practice, and we were thus able to see for ourselves the very great covering power and good definition afforded, even when the lens is used to cover a plate much larger than that for which it is listed. Messrs. Houghtons make their offer through the photographic dealers throughout the country, from whom circulars more fully describing the new "Ensign" anastigmat and the "Koilos" shutter may be obtained.

"SOHO" REFLEX CAMERAS.—Messrs. Marion and Co. have added the series of "Soho" reflex cameras one of stereoscopic size, taking plate of  $5\frac{1}{2}$ in. to  $3\frac{1}{2}$ in. They fit with special removable screens and divisions, permitting the use of two paired lenses. The stereo vision is so constructed as to work with the movement of the mirror, while it can be removed in a moment when desired. The price of the new reflex, with three double backs, stereoscopic screens, and divisions, is £14 10s., including the mounting of two paired lenses, but not the lenses themselves. With 2 Cooke Series III.,  $f/5.5$ , paired  $4\frac{1}{2}$ in. focus, the cost is £22; with 2 Zeiss-Tessar,  $f/6.3$ , paired  $4\frac{1}{2}$ in. focus, £23 18s.; with 2 Goerz-Dagor,  $f/6.8$ , paired 5in. lenses, £25; and with 2 Ross homocentrics,  $f/6.3$ , paired 4in. focus, £28.

AUTOCHROME PLATES.—Messrs. A. E. Staley and Co. announce that they are prepared to supply Autochrome plates in the English sizes their usual customers.

"FOR THIS RELIEF, MUCH THANKS."—At the time of writing, a large portion of the large edition of "Colour Photography with the Lumière Autochrome Plates" has reached the hands of individual readers. The appearance of the publication, so we have learned from many quarters, has been welcomed by those wishing for a concise, reliable instruction in the process. Not only so, it has proved a boon to those desiring to escape from the ubiquitous questioner clamour for information as to the why and wherefore of the process. The photographic dealers and professional photographers have found it an admirable means of saving themselves the trouble of lengthy explanations. The small sum of 2d. cannot be an obstacle to the purchase of a brochure which explains the mechanism of the Lumière process, and gives all the directions necessary for its practice. The firm of Messrs. Houghtons, Ltd., we would repeat, is the sole wholesale source of supply, and orders for the publication could be addressed to them at 88-89, High Holborn, London, W.C., or at 70-78, York Street, Glasgow.

## New Materials.

"Ivory Matt" Bromide Paper. Made by Thomas Illingworth and Co., Ltd., Willesden Junction, London, N.W.

In this new brand of their bromide paper, Messrs. Illingworth have produced a printing medium worthy of the attention particularly of professional photographers. The paper has a delicately matt surface, and it supplies prints of fine purity in the whites. Its great range of gradation in conjunction with these two qualities fits it for the great majority of subjects, but it is especially suitable for producing the smaller sizes of portraits which have a handsome appearance on both the untreated and sulphide-toned paper. The amidol or metol-hydroquinone developer is specially suitable for the new paper, and if the instructions are followed, "Ivory Matt" certainly gives results of the first degree of excellence.

Christmas Mounts. Made by Bartons', 114, Golden Hillock Road, Birmingham.

We have seen many selections of mounts and folders intended for the reception of photographs to be ultimately posted as Christmas greetings, but we can honestly say that, despite the undoubted care bestowed upon their production and the money paid for colour printing, none of them have ever approached the effect obtained by these productions of Messrs. Bartons' in an infinitely simpler way. The mounts consist of the fine textured papers which Messrs. Bartons' have supplied of late for the purposes of photographers with an eye to the tasteful presentment of their works, and contain only a simple design printed in a pale ink and enclosing only the simple words, "Christmas Greetings." The average Christmas card, photographic or otherwise, commonly sins in being too effusive, and the simplicity of Messrs. Bartons' designs is in nice accordance with the brevity of the wording, and the whole effect we think of a photograph, particularly if the latter is dry-mounted to its support, will be as fine as is obtainable in a shape intended to pass through the post as a Christmas souvenir. We have no particulars of the prices of the mounts, but they are obtainable on application to Messrs. Bartons', at 114, Golden Hillock Road, Birmingham, where also we imagine our professional readers may be able to obtain samples of the different styles. We should strongly recommend them to do so.

The Pictorialist's Outfit. Supplied by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

It is remarkable that the idea which has been embodied in this outfit by Messrs. Griffin should never have occurred to any other of the many firms catering for that creature of modern growth—the pictorial photographer. However, that is not to say that it is Messrs. Griffin who have been behind in the matter, for their introduction follows closely on their entrance into the business of catering particularly for photographers of this class. In the little outfit which they offer they include a bottle of matt varnish, of retouching medium and of local reducer, which appears to be of the "Baskett" type containing a spirituous liquid with a fair proportion of abrading matter in suspension. They also provide two fine spotting brushes, an HB and BB pencil, and a sheet of papier-minerale, together with a convenient palette and spotting colours of three tints. It may be questioned whether the methods of control are quite as much in favour as they were two or three years ago; indeed, Messrs. Griffin, as much as anybody else, have tolled the death knell of these methods by their commercial introduction of the oil process, which provides all the control—much more than can be obtained by these means—with far less trouble. Still the outfit is bound to be of service to many whose desire to improve a negative is based only on technical reasons, and is not associated with any particular pictorial aspiration. The materials supplied in the set before us can be heartily recommended to such as these. The price of the set is 2s. 9d.

WATFORD CAMERA CLUB.—The fifth annual exhibition of the above club will be held in the Corn Exchange, Watford, on October 30 and 31, entries closing October 24. Mr. A. Horsley Hinton will judge the exhibits, and silver and bronze medals will be placed at his disposal for award. Two special awards also are offered—namely, a silver plaque in the champion class, open to all, and a special gold medal given by the president for the best exhibit in the members' classes. Entry forms are now ready and may be obtained on application to W. R. Gunton, 139, High Street, Watford.

## CATALOGUES AND TRADE NOTICES.

THE LUMIERE Co., 89, Great Russell Street, London, W.C., have issued a new edition of their formulae for development, including those for the new "Autochrome" plates. The instructions for the use of the latter are also given, together with a useful series of hints on failures and remedies. The booklet will be sent post free to any applicant.

MESSRS. MARION AND Co.'s list, as a comprehensive catalogue of photographic apparatus, merits a prominent reference on the re-appearance of a new edition. In the present instance, Messrs. Marion have contrived to further reduce the number of pages without sacrificing the usefulness of the list for the purposes of the photographer who is concerned only with providing the best tools for his work. The amateur will not find here particulars of every accessory which human ingenuity has devised avowedly for his assistance, but he will find, very well arranged and amply illustrated, an excellent selection of standard apparatus and materials. A convenient volume, which is issued to the trade only, lists many fine art publications, water-colour drawings, and frames and stationery, which is an important part of Messrs. Marion's business. The two lists should certainly be at the elbow of the professional photographer, who, we believe, may obtain either of them on application to Messrs. Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

A USEFUL 16-page pamphlet reaches us from Messrs. Ross, Ltd., 111, New Bond Street, in the shape of particulars of the fitting of the firm's well-known "Homocentric" anastigmat lens to popular types of hand cameras. The list gives the size of lens most suitable for the various Kodak and Premo cameras, with the prices of the complete instruments thus fitted.

MESSRS. PERKEN, SON, AND Co., LTD., 99, Hatton Garden, send us two very timely lists of theirs which we can emphatically suggest should be in the hands of photographers equipping themselves for the winter season's work. The catalogue of enlarging apparatus using artificial light specifies the various instruments and accessories in which Messrs. Perken have embodied years of experience. The practical value of these pieces of apparatus is too widely recognised to require further commendation from us. The list of projection lanterns and lamps, jets, and attachments is not the largest, but it is all the more useful on account of its inclusion of only the most reliable articles for the lanternist. Both catalogues are sent free by Messrs. Perken.

ILFORD PLATES.—The latest edition of the Ilford plate handbook is worth procuring if only for the beautiful example of decorative photography which adorns its first page and is an example of the camera applied to draw attention to the notable Ilford manufactures. The book specifies the particular characteristics of the Ilford plates, supplies a useful table of exposures, and advises on the proper illumination of the dark-room. Moreover, it offers a reasonable and assimilable chapter of instruction in the development of a plate with pyro-soda, explains what to do in cases of incorrect exposure, and gives one or two developing formulae, hydroquinone, metol, amidol, metol-pyro, and metol-hydroquinone, which should be noted by those who fight shy of pyro. Notes on intensification, reduction, and other expedients for improvement conclude a most useful and precisely worded book of instruction, a book which every plate user may consult with profit, and may recommend to a beginner in doubt. The book may be had gratis from photographic dealers everywhere, or for one penny stamp, direct from Ilford, post free.

THE LINKED RING AT HOME.—That most enjoyable function of the exhibition season, when the members of the Linked Ring are at home to their friends, took place at the exhibition at 5A, Pall Mall East, on Tuesday last. A large number of guests, representative of the most varied interests in photography, assembled in the home of the Photographic Salon, and were unanimous in praise of the Linked Ring's hospitality. One cannot ask for more than to meet one's friends and to spend an hour with intervals of genuine entertainment, and the Linked Ring's infallible tact in stage managing their evening provided every opportunity for chatting awhile with old friends and listening with them to such accomplished entertainers as Mr. Arthur Helmore, whose burlesques of actors and mock sermon are some of the things which will bear repetition at many another Salon "At Home."

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 18.

Aberdeen Photographic Association. "Chemical Theory and Photographic Practice." Robert Glegg, B.Sc., F.I.C.

MONDAY, OCTOBER 21.

Manchester Photographic Society. "Among the Dutchmen with a Camera." J. Fergusson.  
 Stafford Photographic Society. "A Simple Method of Development for Beginners." Henry Cliff.  
 Bradford Photographic Society. "'Wellington' Iso. Plates and S.C.P." Harry Wade.  
 South London Photographic Society. "Animal Sculptures in Church Architecture." Geo. C. Druce. Monthly Competition—(Prints).  
 Slough Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."

TUESDAY, OCTOBER 22.

Redhill and District Camera Club. "Theory and Practice of Time Development." W. F. Slater, F.R.P.S.  
 Birmingham Photographic Society. Annual Meeting.  
 Manchester Amateur Photographic Society. "'Wellington' Iso. Plates." Harry Wade.  
 Leeds Photographic Society. "The Platinotype Process." The Platinotype Company.  
 Keighley and District Photographic Association. "A Visit to the Fjords of Norway." J. Skirrow.  
 Wimbledon and District Camera Club. "Crossed Swords Pigment Paper." F. Hart.  
 Hove Camera Club. "Rotary 'Carbograph' Paper."

WEDNESDAY, OCTOBER 23.

Everton Camera Club. "Intensification and Reduction." Messrs. Stonehouse and Others.  
 Coventry Photographic Club. "The Carbon Process." H. J. Goodwin.  
 Croxson Camera Club. Lantern Night.  
 Leeds Camera Club. "Exposure and Development." J. Fred Seaman.  
 Edmonton and District Photographic Society. "Rotary 'Carbograph' Paper."  
 North Middlesex Photographic Society. Fifteen Minutes' Lecture Competition.  
 Central Technical College Photographic Society. "The Leading Principles of Velox Manipulation." A. W. Green.  
 South Suburban Photographic Society. "Figure Work." E. T. Holding.

THURSDAY, OCTOBER 24.

Liverpool Amateur Photographic Association. "Flower and Fruit Photography." Edward Seymour.  
 Hull Photographic Society. "Beverley Minster." Rev. W. E. Wigfall.  
 North London Photographic Society. "Steps Towards Picture Making in Photography." H. Snowden Ward.  
 Handsworth Photographic Society. "Aston Hall and the Holte Family." E. Timings.  
 Richmond Camera Club. "Röntgen Rays." Dr. Rodman.  
 London and Provincial Photographic Association. Annual Supper.  
 Longton and District Photographic Society. "The 'Wellington' Iso. Plates." H. Wade.  
 Woolwich Photographic Society. "Rotary 'Carbograph' Paper."

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

## COMMITTEE MEETING.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, 11th inst. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, H. J. Hull, A. Mackie, H. S. Mendelssohn, D. Prodder, Lang Sim, R. Fellows Willson, H. A. Chapman, J.P. (Swansea), P. Lankester (Tunbridge Wells), and T. C. Turner (Hull). In the absence of the President, Mr. S. H. Fry occupied the chair.

The Hon. Secretary reported that the September number of the "Circular" had been posted to members since the last committee meeting, and that the invitation to contribute to the P.P.A. Exhibition to be held at the office of the "B.J." in February next had been sent out, and were being well responded to. He also said that he had visited Mr. Jacolette on the previous day, and regretted to find that his progress towards recovery was not as rapid as they would all wish. He was instructed to convey to Mr. Jacolette the regret at his enforced absence, and best wishes for his speedy return to health.

The remainder of the meeting was occupied in the discussion of applications for advice, etc., made by various members of a nature that cannot be reported.

## MEMBERS' MEETING.

At the members' meeting which followed the chair was occupied by Mr. Alfred Ellis. A paper was read by Mr. Edgar Scammon on "Advertising in Professional Photography: Does it Pay?" and an interesting discussion ensued.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting held on October 10, 1907, Mr. H. C. Rapson in the chair, Mr. Seymour lectured upon flower photography. In his work Mr. Seymour used a 12-10 camera, and focussed the nearest part of the subject, stopping down until all was sharp—as he thought it should be in flower work. The subject was pinned to the background, and if any leaf was required where it could not be pinned, a touch of glue did the trick. In some cases twenty to thirty pins were used, varying from those  $\frac{1}{4}$  in. long to the longest blanket in Pansies he always wired to make them take the position desired.

The lighting was governed by white art muslin, which was stretched over the source of light, and the backgrounds were of grey, brown, dark green, or white cardboard. The subject was pinned to it in order to obtain the shadows essential to a successful result. The background and subject were turned to an angle from towards the light as seemed desired.

The darker the flower the darker the background, and with delicate subjects the lighter backgrounds should be used. Do not, said Mr. Seymour, spare the knife: trim off all unnecessary leaves. The lecturer stated that he used ortho plates, but very seldom a green. Time development he had read about, and thought pretty, but it failed him in practice.

His method was to give very full exposure, even to over-exposure; and he then developed with a strong pyro developer without soda, and weak in alkali. Immediately the highest light attained density, he plunged the plate into the fixing-bath. If the result was too flat, he built up afterwards by intensification, in this way obtaining each value in its proper gradation. His exposures for soft. were 20 sec. at  $f/16$  in the strong light; to brighten the greens he damped them with water just prior to exposure.

In addition to the many prints that were on the table, Mr. Seymour showed some 120 slides, some of which were exceedingly fine; but one could not help thinking that very many would have been vastly improved by the judicious use of a light-filter, the greens being in many cases too dark.

Mr. Haddon did not think that the best results were obtained by the use of strong pyro, and he thought that the developer should be the reverse, viz., weak in pyro, for the finest results. Nor did he see the need to pin the subject to the background. He suggested that a sheet of glass with the background at a little distance would be an improvement. Mr. Seymour said that in some cases he did hate his developer, but in nearly all cases he over-exposed, hence a strong solution.

**CROYDON CAMERA CLUB.**—Mr. A. W. Green, representing Messrs. J. Griffin and Sons, gave a demonstration last week of the Rawlins printing process, every step necessary to successfully work it being clearly and ably pointed out. The process being now well known, it will be sufficient to summarise one or two points dealt with by the lecturer, and not included in the instructions for working the process issued by Messrs. Griffin. In the first place, Mr. Green laid stress on the desirability of employing a suitable gelatinised paper for operating upon. That worked out by Mr. Rawlins was the outcome of many experiments, and liberties could be taken with it, which might lead to disaster with other substrated supports. Single-transfer papers, for instance, sometimes recommended, did not permit of the pigment being cleaned off in case of error, and a fresh start made. There was also the ever-present danger with other substrata, of the gelatine pitting under the action of the brush, with a resulting spotting of the prints. The usual artists' pigments, the lecturer said, were not ground fine enough, nor were they of sufficient consistency; they, moreover, were slow driers. The Rawlins' special oil-pigments overcame these objections. The fitch brushes recommended must have natural bristles, and for this reason were more expensive than brushes with "beared" hairs, which split in use and would not then work satisfactorily. Hog-hair brushes might, however, be employed for broad effects were sought. Mr. Green, in the course of his remarks, slowly built up some capital oil-prints, at the same time illustrating various methods of controlling results.

In the earlier part of the evening Dr. Mees introduced yet another plate. This, he genially observed, would probably not be the

faintest use to his hearers, though it had undoubted theoretical interest, which he might dilate upon later in the session. The new-comer possessed red and blue sensitiveness, but was quite blind to the green. He proposed that the following experiment should be carried out by those willing to undertake it. He had with him several boxes of plates in sets of three. One in each set contained ordinary plates; these were, of course, "wrong" one end of the spectrum. The next box in the set contained the "theoretically interesting" plates, and a light-filter cutting out the blue, with which they were to be used; consequently, compared with the ordinary plates, they would be "wrong" the other end of the spectrum. The third box contained Wratten's "panchromatics," and an adjusted "correct luminosity" filter. Comparative identical exposures were to be made on the three plates, and the results shown on a subsequent occasion. Several members undertook to carry out the experiment, which should prove an instructive one. At the conclusion of Dr. Mees' remarks a member rose and suggested that Messrs. Wratten might usefully carry the matter a step further, by issuing a plate totally insensitive to the visible and invisible rays of the spectrum. Apart from certain practical disadvantages, that bugbear of the modern photographer, viz., the erroneous translation of colour-values, would be rendered impossible, and in addition all operations could be carried out in broad daylight, in itself no small an advantage. This week a lantern-night is announced, with a free distribution of samples on a grand scale, which should ensure a record attendance.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On Wednesday, October 9, Mr. F. Martin-Duncan, F.R.P.S., delivered a most interesting lecture on "Denizens of the Deep." A most enjoyable evening was spent, and those interested in the subject may like to know that a book of Mr. Martin-Duncan's is shortly to be published, bearing the same title as his lecture—viz., "Denizens of the Deep."

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—Over fifty members and friends were present at Plough Hall, High Street, Lewisham, on Wednesday evening, to listen to a stimulating lecture by Mr. H. Snowden Ward, editor of the "Photographic Monthly," and a well-known judge at exhibitions. Mr. T. K. Grant was in the chair. Mr. Ward's subject was "Points for Picture Makers," and in delightfully informal, humorous style he gave what he described as a "chat," suggesting rather than prescribing the forms and arrangements which go to the making of a successful picture. The old symbolists, he said, held that the perpendicular line represented virility, energy, strength, movement; the horizontal line, quiescence, calm, repose. So if a pictorialist wanted to make the most of a scene suggesting action, motion, strength, it was advisable to use the upright picture, employing the horizontal form where it was desired to suggest repose. The pointed church spire and the squat, square church tower were graphically used to illustrate this point. Discussing and illustrating the various arrangements of line and mass in a picture, some obviously pictorial and some the reverse, he suggested that for some reason, which he left it to his hearers to explain, a picture is more effective and more likely to be accepted at the exhibition if the principal object of interest is placed on the right of the canvas than if it happens to be placed on the left. Further, he suggested that a point near the top right-hand corner was the "strongest" point in the picture at which to place the principal object, much stronger even than the top left-hand corner, as might be seen by reversing the arrangement. The reason of that, too, he left his audience to decide. From these interesting considerations he passed to the question of relative tones, and, alluding to the difficulty of getting by photography the correct tone for objects of a reddish tinge, illustrated his point by slides of two pictures by Miss Kate Smith, whose tone rendering was usually perfect, but who in the first of these represented the brown sails of a yacht in full sunlight by a tone that was almost black, and in the second similarly falsified the tone of a chestnut horse. On the other hand, he showed slides of photographs by the same clever artist, in which the tones were magnificent, and strong sunlight was luminously represented without the usual accompaniment (in photographs) of pitch black shadows. After a brief discussion a hearty vote of thanks to the lecturer concluded the proceedings.

## News and Notes.

**AUTOCHROME PLATES IN NATURE STUDY.**—Mr. Martin Duncan should be assured of a large audience when, on Thursday next, October 24, he gives the first of the weekly lectures at the Blenheim Club, taking for his subject "The Application of Autochrome Plates in Natural History." Mr. Duncan will exhibit a series of autochrome slides on the screen, including a number of living subjects. He may justly claim to be the first to apply the plates to scientific work.

**FIRE AT A STUDIO.**—A fire broke out last week in the studio of Mr. G. A. Coulson, photographer, of Lower High Street, West Bromwich. The studio and its contents, including a number of valuable cameras, were completely destroyed. The damage is heavy, and is only partially covered by insurance. The cause of the outbreak is unknown.

**DRESDEN PHOTOGRAPHIC EXHIBITION, 1909.**—A competition has been arranged in connection with this proposed exhibition. The committee, being anxious to obtain an artistic poster, are offering prizes to the amount of £125 (first prize £50) for competition amongst both painters and photographers. It is anticipated that the value of the prizes will ensure a quantity of work by first-class artists in both professions being entered. Particulars may be obtained, gratis, from the offices of the exhibition, Neumarkt 1, Dresden-A.

**PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.**—Photographic and other societies in the county of Surrey will doubtless be interested to learn that a lecture entitled "The Camera as a Historian—County Record Work," which is illustrated with lantern slides, has been prepared for circulation by the council of the above association. Arrangements have already been made for delivery of the lecture at meetings of several societies affiliated to the Survey, but as there are still a few vacant dates the secretary would be glad to hear from any society in the county who would care to secure it. Those interested in the matter should apply as soon as possible to Mr. Frank F. Wood, 11, Milton Road, Wallington, who will supply all particulars.

**HOVE CAMERA CLUB.**—This is the last of the three "Southern" exhibitions, and will be held at the Town Hall, Hove, December 11 to 14, entries closing December 3. Pictures are sent free of charge between Southampton, Southsea and Hove, and there are reduced rates for entries at all three exhibitions for which a special entry form is provided. Mr. R. Child Bayley will judge the Hove exhibits, and a French plaque, entitled "Salut au Soleil," will be placed at his disposal for award in the open classes. Entry forms are now ready and may be obtained from the Hon. Sec., Mr. Stanley Read, 12, Old Steine, Brighton.

**FORTHCOMING.**—Among the publishers' autumn announcements we see that of a volume "Photography," by A. Watkins, to be issued by Messrs. Archibald Constable and Co., Ltd. "Photo-Chemistry," by S. E. Sheppard (Longmans), is presumably the volume of which Dr. Sheppard is joint author with Dr. C. E. K. Mees.

**SOUTHAMPTON CAMERA CLUB.**—The prospectus and year-book for the season 1907-8 provides evidence of Mr. S. G. Kimber's persistent energy. Among the lecturers at Southampton are Messrs. E. Seymour (Floral Photography), G. E. H. Rawlins (the oil process), C. H. Hewitt (Architecture), C. B. Howdill (Series), and Henry J. Comley (Colour-Photography on three-colour carbon and "Autochrome" plates).

"**PHOTOGRAPHISCHE INDUSTRIE**," our Dresden contemporary, which, while being the organ of the photographic trade in Germany, devotes itself unremittingly to the scientific side of photography, has now secured for the occupancy of its editorial chair Herr K. W. Wolf-Czapke, for many years on the staff of the "Prager Tagblatt," and a recognised authority on the Continent on colour-photography. We anticipate finding in our contemporary in the future a due share of space allotted to the coming innovations in colour work.

**R.P.S.**—The following lectures will be delivered at the New Gallery:—Saturday, October 19: "My Experiences in the Jamaica Earthquake," by Vaughan Cornish, D.Sc., F.G.S., F.C.S., F.R.G.S.; M.J.S. Monday, October 21: "Two Benedictine Ministers," by E. Harvey Piper, Hon. M.S.A. Thursday, October 24, "Bird Hunting in the Balkans," by R. B. Lodge.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—The above association hold its annual supper on October 24, 1907, at the Hotel Boulogne, 27, Gerrard Street, Shaftesbury Avenue, W., when any friends and visitors will be heartily welcomed. The hon. sec., Mr. E. R. Human, will gladly answer the inquiries of any who would like to be present.

**MESSRS. STALEY** notify us that owing to the increased cost of glass etc., the prices of the "Euryplan" lenses have been slightly raised. A circular of the revised prices may be obtained on application to Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

**PHOTOGRAPHIC LANTERN LECTURES.**—Many a society secretary or any one who has to provide lecture entertainments for the public will be grateful to us for drawing attention to the prospectus of lectures by Mr. A. H. Blake, M.A., of whose photographic qualifications there is no need for us to write: the exhibitions and the reproductions of Mr. Blake's always original work speak for themselves. Mr. Blake's charm and mastery as a lecturer may not, however, be equally well known even to admirers of his photographs, and for that reason we may refer to the six photographically illustrated lectures which he is prepared to deliver. "Walks with a camera in London" will probably delight photographers as much as the others, but Mr. Blake's delicious humour, his fine sense of presenting old things in new ways, and his eye for the picturesque in familiar subjects, make him a most welcome lecturer to any cultivated audience. Particulars of Mr. Blake's engagements are obtainable from him at the Blenheim Club, St. James's Square, London, S.W.

"ON THE HILLS OF HEALTH" is the title of a booklet forming No. 1 of "Out of the Fog" series; which Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., are issuing with a special view to the requirements of those who are desirous of spending their week-ends in some spot within easy reach of the metropolis over which the fog-demon has no control, at any rate, for the present. The little book deals, in narrative form, with the more picturesque spots in and around Caterham Valley, and is well worth the small outlay of 6d., for which it can be obtained from the above firm, at 4, Stationers' Hall Court, London, E.C.

## Commercial & Legal Intelligence.

**CHARGE AGAINST A CANVASSER.**—Charles Hodge, at one time a Penarth chimney sweep, but of late years trading as the Phoenix Photographing Company, 5, Tewkesbury Street, Cardiff, was charged at Penarth last week with larceny by means of a trick. The allegation was that defendant went round canvassing for orders for enlargements, in some cases getting as much as 10s. or 15s. by instalments, and the enlargements never came to hand. A large number of witnesses were called, and gave evidence bearing out this statement. Mr. Stephens, for the prisoner, said he would reserve his defence, but he would give a satisfactory answer to all the charges. Prisoner was remanded till the Quarter Sessions next week at Swansea.

**RAILWAY CARRIAGE PHOTOGRAPHS.**—At the Lewes County Court last week Benn and Cronin, photographers, London and Southwick, sued Harcourt Smith, Uckfield, and Edgar Smith, Hailsham, each for £3 for advertisement views displayed in the panels of railway carriages. The question in dispute in both cases was the wording of the contract note. Plaintiffs alleged there was no stipulation that the views should be displayed in compartments of a certain class, and they could not dictate to the railway company. Harcourt Smith did not consider the exhibition value of the views was as great in one class as in another, from his business point of view, and in consequence he refused to pay the account. He did not consider the value of the advertisements in second-class equal to third-class. Edgar Smith said he was promised by the firm's representative that the views should appear in the trains running between Tunbridge Wells and Eastbourne—about thirty miles run. Instead, they were only placed in a local train running between Hailsham and Polegate. Plaintiffs brought a witness to prove that the views were seen in a railway carriage at Eridge the previous week. His Honour, in giving judgment for plaintiffs for £2 and costs in each case, pointed out that no particular class or trains was stipulated in the contracts.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. Broadhead, 12, The Market Place, Lynnhford Road, Farnborough, Hants. Photograph of a Group taken to Commemorate the Marquis of Granby's Coming of Age.

Stereoscopic Post Card Co., Ltd., Essex House, Stratford, London, E. Two photographs of the Kirkcaldy Trades Bazaar.

Harrison, The Studio, Skipton Road, Barnoldswick. Photograph of the Bazaar and Communion. Decorated for Harvest Festival at the Baptist Church, Barnoldswick.

Wallace, Eskbank Road, Dalkeith. Photograph of Pierre, Lanolade. G. Webber, 1, Brock Street, Lancaster. Photograph of the late T. F. Fenwick, Esq.

Harv. 32, Briardale Road, Seacombe, Cheshire. Photograph of the R.M.S. "Lusitania."

H. B. Munslow, 96, Cambridge Street, Norwich, Norfolk. Photograph of the Interior of the Roman Catholic Church, Bournemouth. Photograph of Log Rolling on the Wensum.

Filkinson, 1, Royal Arcade, Norwich. Three Photographs of the Norwich City Football Club, one with Directors and Staff for Season 1907-8.

Turner, Railway Inn, Stafford Street, Hanley, Staffs. Photograph of the Hanley and District Military Band.

Watkins, 18, Swan Street, Brechin. Drawing of Old Arms of the Long Defunct Family of the House of Edzell. Edzell, Forfarshire (1558).

Ward, Stoneyhurst, Southbourne Road, Pokesdown, Bournemouth. Photograph entitled "Pokesdown Beach."

F. T.—On developing, the "Watkins Manual" (Watkins Meter Co., Hereford, 1s.); on studio work, "Lighting in Photographic Studios," by P. C. Duchochois, 1s.

F. CORN.—We cannot refer you to a better formula than the following:—Pale gum resin, 200 grs.; gum dammar, 90 grs.; gum mastic, 20 grs.; oil of juniper, 1 drachm; oil of turpentine, 2 to 4 ozs. This is the formula recommended by Mr. Arthur Whiting in his book "Retouching."

ARTIFICIAL LIGHT.—I am in a house where there is no gas, and will feel obliged if you will kindly tell me (1) whether there is an apparatus for producing artificial light to enable me to give exposures in ferrotype work. (2) Is there such a thing as reflector that can be placed inside the camera for viewing things right way up?—TINTYPE.

(1) The "Ideal" lamp of Messrs. Houghtons should do what you require. (2) Except in conjunction with a focussing screen on the top, or in the side of the camera—a reflex camera, in fact, there is not. A mirror is sold, however, to fix outside the back of an ordinary camera, and permits of the image being viewed in the natural position. Messrs. Houghtons, we believe, are the makers.

YOUNG SILVER.—Is there any chemical obtainable with which I can throw down the silver in a fixing bath (for plates only) that does not cause a smell? If so, how much would I require to "throw down" the silver in a tank holding three gallons? Also how long would it take before I could run off the surplus bath? I have used "sulphuretted potash" for obtaining residues before, but the smell has been objected to.—W. S. G.

You can try zinc dust, which is a powerful reducer of the silver, but is not a great improvement over the sulphide in freedom from odour. Use a handful in the quantity you name; an excess will do no harm. Sulphide, however, is the best material.

FLUORIDE.—(2) Can you suggest a good wide-angle lens for flashlight work, one that will cover well at a large aperture, and not give much distortion, for 12 x 10 and 15 x 12 work?—J. S. C.

(1) Maloni's Patents Co., Ltd., Ayer, N.B.; Houghtons Ltd., 3-89, High Holborn, London, W.C.; the Tress Co., 42, Oxford Street, London, W. The Schroeder lamp and particulars of it are obtainable from Messrs. Fallowfield, 146, Charing Cross Road,

London, W. (2) We cannot. If you require a wide angle you must be content with a moderate aperture. The distortion depends on the standpoint of the camera.

ANGLE OF VIEW.—The print we send has both ends, it would seem, out of focus. The stop was  $f/16$ . (1) Should you think a shorter focus lens, say a wide angle, would suit this class of photography better. (2) What is the largest aperture, should you say, that could be used for taking a line of men, same as print, so that every man can be defined clearly? This is important to us because in winter instantaneous work is necessary.—SECTION.

(1) Certainly not, unless you are confined for space, which, we take it, is rarely the case. We advise you to use a lens of focus at least the length of the plate. This, at  $f/6$  or  $f/8$ , should cover sharply from side to side. (2) As just explained, it depends on the focal length of your lens. A good 12-in. anastigmat will cover a 12 x 10 plate from corner to corner.

WARNER-POWRIE PLATES.—Can you kindly inform me when the Warner-Powrie plate will be obtainable on sale, and where?—E. Y. E. N.

We are not yet in a position to say. We shall keep our readers au courant with the process as information reaches us.

T. H. PEMBERTON.—From the Lumière Company, 89, Great Russell Street, W.C. See our advertisement pages.

AMATEUR.—On receipt of name and address we will answer your query as to a cracked negative.

ELECTRIC.—(1) If a few ordinary incandescent burners are in the neighbourhood of the mercury-vapour tubes, the unpleasant effect of the light is neutralised. (2) One enclosed arc or two mercury tubes.

A QUESTION OF ACCOUNT.—Some two or three months ago, according to instructions, I cycled out about five miles to photograph three bulls. The customer wished me to expose two plates on each, which meant that I used six 10 x 8 plates. It was not an easy task, but I got what I consider to be a good picture of each bull. I submitted proofs in the course of a few days, but received no answer, and after waiting a week or so I wrote to the effect that, having received no answer, I feared, lest they had gone astray; would Mr. ——— kindly reply in answer to my inquiry. This, however, failed to get the reply, so after a short time I again wrote to say that I trusted no misunderstanding had arisen, and any order would be promptly attended to. This again failed, so will you kindly tell me if I can demand payment for same and plates used, and would you consider 12s. 6d. too much to charge? I have no doubt he will resent paying, but surely I shall be in the right by sending in bill.—READER.

You seem to have acted in a very unbusinesslike way in the matter by letting it rest for so long. Your best way now will be to render an account for the pictures supplied, at your usual prices, and demand payment, and if that is not forthcoming sue for the amount in the County Court.

MULTIPLE PORTRAITS.—Will you kindly help me with regard to how to proceed to obtain a negative of a person in two or three different positions on one and the same plate?—J. B. RUNDLE.

The usual method of obtaining two or more portraits of the same person on one plate is to have a repeating back to the camera. A very convenient form of this is the "Multisecto," sold by Messrs. Fallowfield, Charing Cross Road, with which you can obtain a dozen or more positions on the same plate. The apparatus was described in the "Journal" for May 31 last.

R. HUNT.—The only thing we can suggest is that you advertise in the "Journal" for the appointment you desire, and stating what you consider your qualifications. We should, however, advise you not to throw up your position to take up photography in the present state of the labour market without due consideration. Do you read the advertisement column, headed "Situations Wanted," and see the wages asked by really experienced men?

STUDIO QUERY.—I am just about to put up a new studio, and should be very much obliged if you could give me an opinion of the following design:—Studio, 30ft. long by 15ft. wide; glass, starting 5ft. from floor, on north side, and extending at an angle of 65 degrees to 14ft. high; six blinds; walls covered light green diaper paper; small dressing-room at entrance end, 10ft. by 8ft.; dark-room for changing plates, 10ft. by 6ft., at other end. Any

suggestions respecting above would be very gratefully received.—STUART B. THOMAS.

The design seems, on the whole, very good, but in place of the blinds 1 and 6 we would suggest that the studio there be made permanently opaque, as light there will never be required. The other blinds will do very well as proposed. The glass need not be carried up to the full height of the 14ft. unless you prefer it. The covering for the walls will be very suitable, and the general arrangements are good.

THOMAS ASHMORE.—A suitable preparation for collotype plates is a mixture of "four ails," 200 parts; syrupy silicate of soda, 10 parts. This is well stirred, allowed to stand for some time, and then filtered through muslin. A gelatino-bromide plate may require a special substratum, the formulae for which are trade secrets.

R. T. ELLIOTT.—Obviously the people to pay you are the people who gave you the order—with the lady's permission. There is probably no copyright now subsisting in the photograph, so that the threats to proceed against you are not worth consideration.

COPYRIGHT.—Can you inform me what steps to take to copyright a postcard which will be sold in Montreal and Quebec?—S. E.

If registered here the copyright should be sustainable in Canada, but the copyright law there is somewhat lax, and we doubt if the protection is worth very much.

INQUIRER.—(1) The pigment films of the Rotary Photographic Company, the three-colour Autotype tissues of the Autotype Company, the Sanger-Shepherd stripping films, and imbibition process; the Uto bleach-out paper. Particulars of all these have appeared in our columns of late. (2) We know of none.

COPYRIGHT.—I shall be glad if you will kindly answer me the following questions, though your valuable columns. (1) How do I proceed to copyright a photograph? (2) If such photograph has been reproduced previous to the copyright have I any claim? (3) Can I stop all sales of reproduction except those issued by me after such copyright if done now?—ANXIOUS.

(1) Fill up the necessary form (from Stationers' Hall, E.C.) and send it, with two prints, and a fee of 1s. (2) No. (3) Yes.

E. FENSKE.—Apply to Sanger-Shepherd and Co., Gray's Inn Passage, Holborn, W.C.

BACKGROUNDS.—I am enclosing a small sample of background, and will be pleased if you could let me know, through the "B.J.P.," what oils or other mediums are used to paint with to get a texture that has no tack (same as sample enclosed), and what would make it glossy as if it was varnished, if wanted? Any kind of hints on painting this kind of background I will be pleased to know, or are there any books published that would tell me?—MANCHESTER.

On pp. 82 of the issue for February 1 and 155 of that for March 1 directions are given for making backgrounds, though not the same as the sample sent. Those who make such as that do not publish their methods of manufacture—it is somewhat a trade secret. However, if that is the kind you desire you will, no doubt, find it more economical to purchase them than to attempt to make them yourself, seeing that they are sold at so low a price. No doubt these backgrounds might be made glossy, if such a thing was wanted, by varnishing them with ordinary wainscot varnish. No books on the subject are published.

PALATINE.—The usual fee is 10s. 6d. for a reproduction up to 6 by 4 inches, or more if the reproduction is larger and the subject of uncommon interest.

THE ADVANTAGE OF BEING 'ANOTHER MAN'S WIFE.—Kindly give your advice upon the following:—If a gentleman brings a lady (not his wife) to be photographed and pays for the sitting, the lady being quite willing for same, can the husband of the lady forbid us supplying any more copies of his wife's photograph to the gentleman who paid for the sitting?—AJAX.

Under copyright law the husband cannot restrain you from supplying copies to the order of his wife's gentleman friend. But it is conceivable that the distribution of the photographs in this way may be an offence under the law of libel. We should advise you to consider the local circumstances of the parties in proceeding further in the matter.

NIGHT PHOTOGRAPHY.—Will you kindly tell me if you can photograph

buildings by night? There is a new chemical works close to house, and I have been asked to photograph it when it is light at night. Will you kindly let me know how it could be done?—ANXIUS.

We can best refer you to the article on night photography by Robert S. Dykes which appeared in the "B.J." for August. You will find in it the very instruction necessary in your case. ELECTRIC.—It would seem that you are using too much reflected light. We could say better from prints, but we should advise you to dispense with some of your reflecting surfaces.

A. G. BOLWELL.—Barton's, 114, Golden Hillock Road, Birmingham. DEAD BLACK, ETC.—I want to make a dead black for wood. I there is a formula on p. 997 of last year's "Almanac," which include Nigrosine V.V.S. I have tried to get it at several chemists and other shops round about here, but no one seems to know what it is. I also looked in "Lloyd's Encyclopedia," but failed to find it in there, so (1) will you say where it can be obtained? Also I want to make some dark slides, and would be glad if you can tell me (2) how to polish mahogany wood (which has not been polished before); or if it would take up too much space in the "Journal," (3) can you tell me where I can get such information from?—ASSINUE.

(1) Any chemist can obtain it if he likes to take the trouble. Write for it to Griffin's, Kingsway, or some other firm that supplies chemicals, such as Townson and Mercer, or Baird Tatlock. (2 and 3) We do not advise you to attempt making dark slides unless you are well equipped with workshop appliances. French polishing requires a good deal of practice, and Dawbarn and Ward, we believe, publish a small handbook on the subject.

PATENTING.—Should I patent a sensitive solution for photography (soluble in spirit)? Should I start a business in which to work the same without patent or with patent? Would you recommend me to employ as patent agents for me?—AMBER.

How can we possibly advise you from such shadowy details? It is against our rule to express an opinion of the status of a patent and of professional gentlemen.

THE THOMAS YOUNG ORATION OF THE OPTICAL SOCIETY.—The above oration has been established for the purpose of providing an annual lecture on some subject connected with physical, geometrical, or physiological optics, and thus to further the development of those branches of science with which the name of Thomas Young is intimately associated. The orator is elected annually by the Council of the Optical Society from persons eminent in the branches of science or technology. The oration is delivered in English, in the autumn of each year at the rooms of the Society or at some other suitable lecture hall in London, and is published in the "Transactions" of the Society. Professor M. H. E. Tscherning, Director of the Ophthalmological Laboratory of the Sorbonne, Paris, has accepted the invitation of the Council to deliver the oration in the Optical Society's lecture hall, 20, Hanover Square, London, W., on Thursday, October 17, at 8.30 p.m., and has chosen for its title: "The Development of the Science of Physiological Optics During the Nineteenth Century."

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of examples of photographic portraiture by artificial light opens at the house of the "B.J." on Friday, November 1.

The exhibition of the Society of Colour Photographers at the house of the "B.J." closes to-morrow (Saturday), at 12.50.

Mr. Arthur Payne gives a formula for a green safe-light, which has been found suitable for handling the Autochrome plates. Mr. Payne lays stress on one important point in avoiding frilling. (P. 803.)

Sir William Abney on the Autochrome process. (P. 804.)

The Society of Colour Photographers. The secretary's report of the past year appears on page 813. The society proposes to hold an exhibition towards the middle of next year.

The Warner-Powrie process. Some equitable criticism of the Warner patent specification has appeared in a German journal. (P. 812.)

The Lumière and Warner-Powrie processes figure in the programme of the Royal Photographic Society. (P. 801.)

In the discussion of Mr. Edgar Scamell's recent paper before the P.A. the value of booklet distribution among customers was strongly emphasised by several photographers. (P. 805.)

One of a series of useful hints on portraiture, in this week's "Amateur Photographer," is quoted on page 816.

Some sound advice from an American professional appears on page 811.

Odourless substitutes for sulphide in sulphide toning have been worked out by Mr. Harry E. Smith. (P. 808.)

Mr. Douglas Carnegie records his experience with a new and delicate method of focussing. (P. 811.)

Mr. Martin Duncan contributes an article on the "Elements of Multi-colour Illumination in Photo-micro Work." (P. 810.)

## EX CATHEDRA.

### The Society of Colour Photographers.

The members of the Society of Colour Photographers should have good reason to be satisfied with their first appearance on the stage of colour photography. Although in a private way among its own members the Society has been steadily at work for the past year, little has been heard of it until the collection which has been brought together at the offices of the "B.J." showed what had been done. As seen from the secretary's report which we publish on another page, the membership has reached quite a creditable total during the year, and there is every evidence that the Society is sufficiently free from the faults of extreme youth to take a serious view of its special subject. In proof whereof may be cited its decision to hold a second exhibition of colour photography in 1908, but in the earlier part of the year (May-June). The exhibition will thus fall at the latter part of the London season, and will still give colour workers a long enough time in which to prepare fresh prints.

\* \* \*

### The "B. J." Colour Supplement.

Colour matters of one kind or another—Autochrome, Warner-Powrie, and others—have compelled us of late to depart from our expressed intention of confining these subjects to the monthly supplement to "The British Journal of Photography." We do not suppose that one reader of the "B.J." or the "Colour Supplement" has objected to the articles on recent developments in trichromy overflowing their suggested boundaries. Yet perhaps we may anticipate the remonstrances of one or two who may remind us of our promise to make the "Colour Supplement" a reference publication of current progress in colour photography. We will do so by adding to the index of the "Colour Supplement" a set of references to articles, etc., which have appeared in the "B.J." in the course of the year. This will be additional to the general annual index to the "British Journal," which, with the "Supplement" index, will be presented with the last issue for the present year. Meanwhile, we would like to say that among other items to appear in the November "Colour Supplement" are two articles:—

"Duplicates of Autochromes by Contact-Printing and Copying." By C. Welborne Piper.

"Actinometers in Exposing Autochromes." By Alfred Watkins.

both of which deal with topics of more than ordinary interest to users of the new Lumière plates.

\* \* \*

### Colour Photography at Russell Square.

One early fixture at the Royal Photographic Society should be certain of a large and interested audience, namely, the demonstration on November 5 of the Lumière Autochrome plates by Mr. T. K. Grant, the

British representative of MM. Lumière. It is doubtful if all who assemble on that date will meet a week later, when an ordinary meeting of the Society is to be devoted to "a discussion of the best methods of advancing the study of photography in colours." It is announced that the suggestions offered at this meeting will be considered by the Council of the R.P.S., though one would have supposed that the Council as a body is better qualified to originate, and act upon, the measures which seem desirable than is a meeting drawn from the members as a whole. Usually the value of suggestions emanating from a meeting which has gone into committee is in inverse proportion to the numbers present. However, we are pleased to see that the Royal is determined to keep in line with advances in colour processes, in further proof whereof it has invited Mr. Powrie to lecture on the Warner-Powrie process on December 3.

\* \* \*

### The New Photographic Society.

In the "Year-book" just issued by the Northumberland and Durham Federation a suggestion is made which may have an influence on photographic societies up and down the country, and may do something to re-vitalise the great numbers which are in a moribund condition. The scheme as announced is evidently advanced with a knowledge of the conditions of many a photographic society, though the outlines still leave us in some doubt as to its precise character. We read that it is an error to suppose members of photographic societies have any wish to hear papers, formal discussions, and lectures of any description; therefore, in the newly suggested society all these are to be sternly prohibited. So also are technics. Only the artistic side of pictorial photography is to be allowed to enter, yet the monthly meetings of the Coterie (as it is to be called) are to take the form of informal soirées, with full liberty to the members to smoke and do what they please, so long as they conduct themselves properly. Meet, smoke, and yet never a word of "shop"! We confess we disbelieve the possibility of any such organisation lasting for ten minutes. We read further that a crusade against the demoralising influence of medals, plaques, etc., is to be a feature in the constitution of the "Coterie," the members of which will pledge themselves to abstain from competing for awards in pictorial photography. There is to be no committee, and no official except the secretary; but when required the whole of the members will act as a committee. The subscription is to be quite nominal; one shilling a year, if possible, but in no case more than five shillings. There is, we think, a good deal of truth in the idea that members of societies

in general have no liking for lectures, and that attend mainly for the sake of associating with kind spirits. Yet how Mr. Arthur Payne, who is mentioned as one of the moving spirits in this new project, expects to hold it to the letter of its suggested constitution we cannot understand. "Art, all Art, and nothing but Art"! can see Mr. Payne powerless to resist putting a friend the way of using an orthochromatic screen properly rendering some other of many services to his photographic brethren; and, as Mr. Payne is the honorary secretary of the suggested society, we hope and believe that the innovation will commence a career of unconditional success by at once violating its own eclecticism making its informal meetings the opportunity for personal chats on any photographic topic which may arise. Photographic societies may watch the experiment with some interest.

\* \* \*

### Cloud and Weather Photography.

In a small book on "Observing and Forecasting the Weather," by Dr. Horner, F.R.Met.Soc., the reader is advised to make use of the camera for recording various types of cloud formation, lightning flashes, damage caused by hail, and the size of extra large hailstones. It is curious that so few photographers seem to take any interest in the photography of clouds, excepting when they use a cloud negative for the purpose of turning a "bald-headed landscape" into an alleged picture. Clouds by themselves are a very interesting study, and are often of an extremely decorative character. The few photographers who have specialised in the photography of "cloudscapes" generally produce a collection of prints that are not only of scientific value, but also of very great beauty and artistic interest. Those who only make the photographs for scientific purposes often spoil the effect by exaggerating the contrasts, but, if this fault is avoided, the results are well worth looking at for quite other than scientific reasons. Of course, for scientific record work, ordinary monochrome photographs are necessary, as reproductions may be desired, but colour records also have their uses, and we have little doubt that a collection of fine cloud studies on Autochrome plates would be a collection well worth seeing. Perhaps some enthusiast will like to carry up this idea. Going back to the scientific aspect, there are several other subjects worth recording besides the clouds considered in the book mentioned above. The effects of windstorms and of local whirlwinds is often very curious. Even in London instances have occurred of clumps of large trees being torn up by the roots while surrounding trees were undamaged. Such an occurrence is well worth

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### SCREEN-PLATE THREE-COLOUR PROCESSES

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1908 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1908 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

### IMPORTANT NOTICE.

Our publishers ask us to inform agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

late or two if the exposures are made before anyone interfered with the debris. Then again, photographic records of floods (which are not very infrequent) and their effects would be of considerable value, especially to those concerned in preventing the recurrence of these inconvenient phenomena.

### PORTRAIT LENSES AND CABINET LENSES.

During the past few months we have had to reply in the answers column to queries from correspondents with reference to old portrait lenses that they have come into possession of. In all cases the instruments have been described as "cabinet" or "carte" lenses, according to their size. From their description, and the probable date of their construction, it is pretty clear that, as a rule, they were not made for either of these pictures, but are of the form of portrait lenses. Before the introduction of the "carte de visite," and later on of the "cabinet," most of the portraits taken were in the sitting position, for which purpose a lens with a very flat field was not required. A certain degree of roundness of field was no detriment; indeed, with some poses it was a decided advantage. When the "carte" picture came in, and full length figures were the order of the day, quarter-plate or half-plate lenses were used for them; but it was found that with them the head feet, and the centre of the figure could not be got into sharp focus at the same time, unless the lens was considerably stopped down. This, of course, entailed a prolonged exposure which could be ill afforded in the wet col-

lodian days. Opticians, of which the late Mr. J. Dallmeyer was the first, put upon the market lenses specially constructed, with a much flatter field than their predecessors, so that all parts of the standing figure could be obtained in approximately good focus. These were termed "carte" lenses. Some years afterwards full length cabinet pictures came into fashion, and the ordinary whole plate lenses were employed for them. But special lenses, possessing the properties of the "carte" lenses, were soon put upon the market. These lenses, like the special "carte" instruments were fitted with Waterhouse diaphragms, which the older forms were not. Hence, it may be taken for granted that when an old portrait lens is met with which is not fitted with central stops, it was not made for either "carte" or "cabinet" portraits, and that it has a tolerably round field. Sometimes one meets with a lens, the name of the maker of which is affixed on the mount beside the opening for the stops. This indicates that the lens was not originally fitted with stops, and that they have been added since. The portion of the mount has been cut out to admit the stops, and the piece bearing the maker's name has been screwed on the side. In such a case it may be fairly assumed that the lens was not specially made for either "carte" or "cabinet" pictures. From what has been said, it must not for a moment be assumed that these old instruments are not good ones, for many of them are really excellent, though they may have a somewhat rounder field than those of more modern manufacture. Roundness of field can be remedied by stopping down, and that the present rapid gelatine plates permit without a very undue exposure being necessary.

## STEREOSCOPIC PHOTOGRAPHY WITH AUTO-CHROME PLATES.

In last week's issue of the "B.J." Mr. Arthur Payne explained the precautions which he had found successful in cutting Autochrome plates to the stereoscopic size and in exposing them. He has noticed the discrepancy of exposures in and out of doors. In this article Mr. Payne gives the formula of a green safe-light which he has found satisfactory in handling the plates, and advises the use of one dish throughout the process as a factor in avoiding frilling.—Eps. "B.J."]

### The Dark-room Light.

Before proceeding to comment upon the manipulation of these plates, I think it advisable to mention that, as a panchromatic emulsion is used, it is essential that great care should be taken to avoid light fog. Many workers advocate the use of a dark light, whatever that may mean, but most photographers are aware that for all practical purposes the work might as well be done in the dark as by means of such a light, which only serves to make the darkness visible. From the first I have used a green safe-light, and have found it to be trustworthy. For various reasons, into which I cannot enter here, such a light is preferable to any other, and I think that it will be sufficient if I state the formula for the fluid I use in my liquid dark-room, only cautioning the reader that it is necessary to work with this light at the lowest possible point consistent with being able to see.

### Green Safe-Light Solution.

Acid green .....	2 parts.
Naphthol green .....	2 parts.
Tartrazine .....	15 parts.
Water (dist.) .....	300 parts.

Use this solution with twenty-five parts of water, and use in a cell 1 inch thick, with the addition of a sheet of ground

### Frilling.

which has been written about this exasperating trouble, but I honestly say that I have not met with it in my own prac-

tice except on one occasion, when I had become careless through familiarity. It is always wise, however, to exercise precaution, and I find the best safeguard to adopt is to paint a narrow strip of the film, about  $\frac{1}{8}$  inch wide, around the edges of the plate with the gum damar varnish that is used to varnish the plates. This varnish may be applied conveniently by means of a little piece of sponge, which is clipped in a slit cut in the cork of the bottle, and the varnish should be allowed to coat the glass edges of the plate as well as the film. It dries rapidly, and development may be proceeded with almost at once.

### Notes on Manipulation.

The plates seem to be prone to produce air-bells, and therefore every care should be taken when applying the developer to avoid their formation. The use of a soft camel-hair brush to remove them from the film will occur to many minds.

This air-bell trouble is, however, met with during all the operations, for if the plate is drained between the various washings and allowed to stand for about a minute before the next solution is applied, they are almost certain to make their appearance. I therefore adopt the precaution of keeping the plate as much as possible under the surface of the solutions, or water, and only pouring off the water just prior to applying the next solution. If, in spite of this precaution, air-bells should appear, they may be removed by carefully flowing water over the surface of the plate, or by means of a soft and clean camel-hair brush.

I find the best method of handling the plates is to use a rather large porcelain developing dish. The same dish is used throughout the whole process, and the plate is removed for examination as seldom as possible. The solutions are flowed over the plate from glass measures, and the wash water is carefully applied by means of a soft flowing stream from an indiarubber hose pipe. The dish must be rocked during the whole of the time that the solutions are acting upon the plate, but only slowly and lightly, so as not to cause a heavy wash of fluid against the edge of the plate, for this is one of the most common causes of frilling.

If a fungoid growth appears in the pyro and citric acid intensifying solution, the solution must be filtered (cotton-wool will answer) before it is mixed with the silver solution and applied to the plate.

I have adopted Mr. McIntosh's method of removing the superfluous water from the plates before they are dried by means of centrifugal force obtained from the use of a process "whirler." It has much to recommend it in practice, and largely prevents the appearance of green stains caused by the water penetrating into the dyed film.

#### Mounting the Plates.

After the plate is dried and, if thought necessary, varnished, it is cut through the middle so that the two halves of the plate may be transposed. A piece of clear glass measuring  $6\frac{1}{2}$  by  $3\frac{1}{4}$  inches is obtained, and, after the rough edges have been removed by drawing the edge of another piece of glass along them, the glass is cleaned. Strips of black needle paper are then fastened with paste upon the glass so as to form a suitable mask, and, as the inner edges of the  $5$  by  $3\frac{1}{4}$  inch plate will be about  $\frac{1}{2}$  inch apart at the centre, the width and position of these paper strips may be easily measured if the two halves of the transparency are laid film uppermost upon a sheet of paper so that the distance between any two points in the two prints is  $2\frac{3}{4}$  inches. The cover glass with the paper mask is set to one side until it is quite dry, and then carefully cleaned, and the two halves of the stereoscopic transparency are mounted in their proper position by means of lantern slide binding strips.

I prefer to use a clear cover glass instead of one made of ground glass, so that the slides may also be used in the optical lantern.

#### Future Developments.

It is hardly possible for such a beautiful process to remain in its present state, for there is ample room for improvement and commercial competition will ensure a progressive movement.

The direction of these improvements, both in the colour screen and also in the emulsion, are not difficult to forecast. As regards the former, we must strive for a more transparent screen with an absence of the black filling which is necessary in a dyed starch grain screen, such as is used in the Autochrome plate. This improvement appears to have been attained in the Warner-Powrie process, where a lined screen is used instead of a mosaic, for the black filling is not necessary when the lines are in juxtaposition, and I understand that the screen itself is more transparent than the starch grain screen, though the dyes are said to require further adjustment. This is, however, a simple matter.

The emulsion will probably be made of greater speed, though this will tend to increase the difficulty in manipulating plates, and it is quite possible that the makers may have seen this difficulty, and are prepared to coat the plates with a more rapid emulsion as soon as the public are sufficiently educated in the use of a rapid panchromatic plate. What is of greater importance at the present moment is for the plates to have more latitude. Here again it is said that the Warner-Powrie process will have the advantage, because these plates may be coated with a thicker emulsion than it is possible to use on the Autochrome plate, where it is necessary to keep the film thin on account of the treatment of the plate following the first stage of development.

Furthermore, there is a demand for a plate from which prints may be made, and this demand is in a measure met by the Warner-Powrie process, for by it transparencies can be made from a negative, and probably in time we may hope to see prints upon paper by the "bleach-out" process. It is necessary for me to say more, because full details of this interesting American colour-plate have been given in "Journal" in a much more able manner than lies within my power. For the nonce, we must possess our souls in patience, trust that our wishes may soon be fulfilled, and, in the meantime, be content with the Autochrome plate. And, really, a marvellous production.

ARTHUR PAYNE, F.R.P.S.

## THE AUTOCHROME PROCESS.

(A Communication by Sir W. de W. Abney to the "Journal" of the Royal Photographic Society.)

LIKE a good many others, I have been trying the Autochrome plates, and, like most, I have been fascinated by the beauty of the results. My attention has, however, been most directed to the scientific side rather than to the pictorial qualities of the plates. With the latter aspect we have to reckon with the coloured substratum, and also with the sensitive film which overlies it. It may be said that both are novel applications of what is already known. The use of three colours in front of the film is on the same principle as the Joly process, but in the Lumière process we have the three colours placed in proper proportions, though at random, on the surface, whilst Joly had his three colours in coloured lines touching one another. The fact that the colours in the Lumière plates are in dots scattered at random makes it impracticable to follow the second part of the Joly process, which is to make a transparency and back the transparency with appropriate coloured lines. This difficulty must have been felt by Lumière, and hence the ingenious plan of turning the negative into a transparency which becomes a unique picture. The method recommended by the instruction issued with the plates for dissolving the silver from the negative after develop-

ment is simple, and succeeds with an ordinary collodion, as do the after manipulations.

#### Overlap in the Lumière Microscopic Filter.

Naturally, one turned to the spectrum to enlighten one as to the colours of the starch grains which form the coloured screen, and also as to the kind of film which lies over the layer of the coloured grains. Pretty exact information was obtained by exposing in the spectrum a plate through its back and following out the manipulations indicated in the book of instructions. Such a transparency shows that the red, green, and violet are comparatively simple colours lying along the spectrum in order, and not overlapping one another when the exposure has been short, but when the exposure is prolonged the strips of colour lengthen out and do overlap, giving a yellow and also a blue. If a line spectrum of sodium, lithium, and magnesium be pressed on the plate below the image of the continuous spectrum in which the three colours are seen, it will be found that the yellow colour is formed in the green of the spectrum, and the yellow sodium D line is shown as red; the blue lithium line is shown as slightly too green. It may be said here that

granules appear to be scarlet rather than red, the green is a pale green, whilst the third colour is slightly violet. In three-colour work the "taking screen" for the red of the spectrum is, in most plates which are sensitive to the red, a reddish-orange. The viewing screen, according to Ives' process, is a monochrome. In the case of the Autochrome, the viewing screen and the taking screen are the same. The impression one gets is that the Autochrome plate a compromise has been made between the colours of the two theoretically perfect screens, and a scarlet that has been arrived at. The divergence from the true orange is but slightly noticeable. The green granule screen appears to be correct, both for taking and viewing, whilst the red is also a slight compromise. By exposing one of the plates with the film side towards the lens the sensitiveness of the silver compound on the plate is readily obtained. It is evidently silver bromide which has been stained with one of the many dyes which have recently been brought before the notice of the photographic public. In what substance the silver bromide is bedded in I have not as yet had time to investigate. The use of permanganate at many stages of redevelopment would scarcely allow it to be of gelatine. Be that as it may, the film is an admirable one, and answers its purpose fully.

### A Method of Duplicating Autochromes.

The drawback to the process is that there can be only one positive from one exposure. There is, however, a plan which admits of any number of copies being obtained on glass, provided a proper three-colour negative has been obtained. Some two or three years ago I showed to the Society a method by which the transparencies from a three-colour negative could be illuminated by pure spectrum colours, the size of the picture being of necessity very small, since the illumination was comparatively feeble. If such an image be thrown on the Autochrome plate we can have as many copies of the picture that we may desire, and they should be all the same. Whether anything would come of using a slide made by the Sanger-Shepherd process I cannot say, but care would have to be taken to avoid blurring from want of contact with the sensitive film. One can see great possibilities from the Autochrome process. Photographers owe a debt of gratitude to Lumière et Ses Fils for the skill and patience which they have exercised in overcoming difficulties which must be patent to all, and giving them a plate which is so readily workable, and which gives them the power of registering colours in a way which has never before been attempted.

W. DE W. ABNEY.

## ADVERTISING IN PROFESSIONAL PHOTOGRAPHY.

The following is the report of the discussion which followed the recent meeting of the Professional Photographers' Association the paper on this subject by Mr. Edgar Scamell read at the and reprinted in an abridged form in our issue of last week.]

Mr. PERCY LANKESTER (Tunbridge Wells) quite concurred in all Mr. Scamell had said. He started reminding them that photography was a profession, and he (Mr. L.) was of opinion it should be known as a profession. During the last few weeks he had wanted to join a golf club, and had applied to several, but all been refused membership, simply because he had been taken upon as being in business, which he considered was wrong. He thought all photographers should endeavour to be thoroughly up-to-date, and should make their studios and reception-rooms as artistic as possible and to represent as much as possible a sitting-room. A good form of advertisement was to be the very best of stationery. He had pleasure in passing and for inspection one of his booklets, which were artistically produced, gave information about the studios, payments children's portraits, and were interspersed with pictures, etc. These booklets he disseminated among the best class of visitors (obtaining their names from the visitors' list) and among the best customers. The booklets cost him £20 for 5,000, and he got it back over and over again as a result of their distribution. He was, of course, always endeavoured to please his customers. If a customer was not absolutely pleased with his pictures, he always tried to get one that his customer was better pleased with. He always got orders from customers who were pleased with his work. He was not of opinion that advertising in newspapers was of any good in the photographic profession.

Mr. H. S. Mendelssohn thought the best advertisement for photographers was to turn out nothing but the best work. That, at least, alone, was the only form of advertisement that would

Mr. T. C. Turner (Hull) was of opinion that the question of advertising was one that really depended upon the type of business which was carried on. The man who ran a business of half a million sitters a year was bound to advertise in one form or other. He agreed with Mr. Mendelssohn that nothing but good work brought its reward, but he thought they should have good shows of their work. Twenty years ago it mattered little to professional photographers what sort of corner they had, but now, if a man was in a good position near one of

the great termini, he had a great advantage over a man in a suburban district. Therefore he imagined the best advertisement for a man was to get into a good position. The time had come when they must choose the best means of advertising a good position, and he thought that was obtained by making a good show. What Mr. Scamell had said about window advertisement was of supreme importance. One often saw good work in a badly-fitted window where the draperies had been allowed to fade, suggesting that the fortunes of the firm itself had faded too. Another important matter was to advertise with the right kind of people. If they wanted to reach a fashionable sinner and secure his or her patronage, care must be taken not to get the picture in the window with people outside that circle. He remembered an instance where a certain fashionable lady had requested a photographer to withdraw her portrait from a show-case. The photographer was unable to understand the reason for her request, and mentioned it to a friend of his, who asked him to show him the show-case. He looked at it, and at once pointed out the cause of the trouble. The particular lady apparently objected to be on show with someone in a different social position. With regard to keeping studios smart, they all knew that the style and objects in a house reflected to a great extent the manner of man who lived in it. The moment people came in they wanted to see evidence of taste in the things around them. The amount of money spent on a studio was in the long run the rock upon which they built. Photographers did not realise that every year it was essential that a large amount of money should be set aside for renewals. Booklets in a very tasteful form might be made the means of advertising. It seemed to be a very good medium, and was infinitely preferable to newspaper puffs. Colour photography, the display of little transparencies in the show windows were a few possible means in which photographers could advertise their business.

Mr. H. A. Chapman, J.P. (Swansea), thought that everything had been said, and said well, by the previous speakers, and he quite concurred with each speaker. The subject was well in hand, and it had been treated in the best manner.

Mr. Prodger said he would like to have the opinion of the

company present as to the difference between a shop-front and a porch, by way of advertisement. Mr. Bridge thought it depended greatly upon the class of work done. Mr. Lankester said he preferred a shop-front, as people liked to look at a photographer's window. Mr. Prodger suggested that a porch was less shoppy. Mr. Chapman said a man frequently made his rent through chance customers looking at his shop window. Mr. Prodger was of opinion, however, that some people preferred to go to a semi-private place than to a shop.

Mr. Edmonds Hull thought a shop had a great deal to do with business, and a shop window should be changed as often as possible. Mr. Lang Sims said circumstances alter cases. There were some people who could not dress a show-case at a door. His neighbour (Mr. Prodger) had one of the finest doorways in Brixton, however. Mr. Rigden (Bowes Park) said that for his part he had come to the meeting to learn all he could, and he was sorry not to find more suburban photographers there that night, as the debate had been very instructive. So far as the particular question went, his opinion as to advertising by means of printer's ink was that it did not pay. As to the question of show-cases versus shop-fronts, he thought the latter were preferable. If you wanted to get chance customers you must make it the easiest possible for them to come into your premises. If they had to go along a long passage and up a flight of stairs, they would not come. He thought railway-station advertising rather a difficulty. Some ladies seemed to object to their portraits being shown in a railway-station show-case as against a window-front.

Mr. Bridge thought advertising in newspapers was not the slightest use.

Mr. Fry thought that photography as a means of livelihood could be regarded from two distinct points of view, viz., the commercial and the professional. Viewed from the commercial standpoint, a shop-front in a first-class thoroughfare would be desirable; but if the photographer wished to carry on his work in a professional manner he did not think that a shop was advisable. He did not believe it possible to take a high professional attitude and be a shop-keeper too; the public would not accord its assent to the combination of ideas, however meritorious the work produced might be. Mr. Scamell had provided the ordinary photographer with some useful hints on advertising. The artist could only rely upon the merits of his work, and hope that a sufficient number of people would appreciate and recommend his pictures.

Mr. Bridge thought that, whether they differed or not, they

were all equally indebted to Mr. Scamell for his splendid paper, and he proposed a very hearty vote of thanks be accorded that gentleman.

Mr. Alfred Ellis, in giving his views, said that when twenty-five years ago he started in business in Upper Baker Street he was informed by a friend that it was a bad street for business and no one had been known to do any good in it. His friend supplemented his statement with the information, however, that if one started business up a mews people would come to you provided your work was good. Mr. Ellis took this fact to heart, and started with a few photographs in a show-case in a little lobby, and got on very well. Opportunity then came to him to take the whole of the premises, with the shop. He was mainly influenced in taking the shop from the fact that at the time he had commenced to take theatrical photographs and hitherto he had had no place to show his pictures. For that reason he had a shop-front, but if he had continued doing an exclusive private business a shop-front would not have been necessary, as a shop-front was not particularly appreciated by private customers, who did not like to have their portraits in the windows. With regard to advertising, he had always found that ordinary letter press printing was no good. Good work was the best advertisement. He had much pleasure in seconding the vote of thanks to Mr. Scamell.

This was carried with acclamation. Mr. Scamell, in thanking the company for their vote of thanks, said he was pleased to find that at least 50 per cent. of the gentlemen present had given their remarks on advertising. From his past experience in London and suburbs with middle-class people he found a shop-front a great amount of use, and he wished he had one now. He had experienced the same difficulty of sitters complaining of their portraits being exhibited, but he always felt safe in showing specimens of children. Mr. Fry had said the photographer should not advertise. He (Mr. Scamell) was very glad to find he agreed with him that the man himself was the best advertisement. As to Mr. Mendelssohn, he seemed to remember that at one time his pictures appeared in all the best illustrated papers, and that at a time when such insertions carried great weight. He suggested that this was a useful advertisement to Mr. Mendelssohn.

The chairman notified that at the next members' meeting, on the second Friday in January, a very interesting lecture would be given by Mr. Henry J. Comley on colour photography, and he hoped that there would be a good attendance of members on that occasion.

## PORTRAITS FROM LIKENESSES.

[The following is the conclusion of the recent address by Otto Walter Beck, commenced in our issue of last week. The writer's argument, as further stated in the volume by him which Messrs. Batsford have published, is in favour of a certain amount of hand-control in the making of commercial portraits, although more might be said as to the extent to which these methods are commercially possible.—Eds. "B.J."] ]

If you wish to avoid difficulties in character portrayal, do not introduce unnecessary accessories. For instance, a man so dressed and posed as this one is difficult enough to render, without placing a chair, table or plants at his side. Notice how the mass of detail in this chair so placed detracts from the attention the figure should have. It at once cheapens our sitter; he loses personality. Only when we have become masters in background arrangements can we use such accessories to advantage. You have often had this experience; a customer brings back photographs and says: "We agree at home that the likeness in these prints is pretty good, but we do not think the pictures natural; we do not like them." You, of course, know them to be likenesses about as good as you can get, but you ex-

press your willingness to try again. Carrying out your promise, you make some other arrangements in pose, lighting, and background, and in a way this objection has been removed. In the first instance you had stumbled upon some combination of lines that brought about an undesirable characterisation, and in the second attempt you tried another scheme that happily minimised this unpleasantness.

Would you not wish to know what causes these unprofitable effects, and would you not look into the future with more confidence if you could see in your results the realisation of your desires and impressions? I have seen refined women made to appear coarse in the photograph, children rendered ridiculous, and men materialistic, by certain background arrangements.

I will bring about a materialistic characterisation in the pose we have before us by employing just such a device as photographers have unwittingly used. Over the upper half of the background I throw a white sheet. This introduction of white has emphasised the chest, at the expense of the head, bringing out the materialistic, the physical. The lower part of the body, being black, sinks into its dark ground, and the lighted flesh of the face drops out of notice into the white tone behind it. We have lost stability in the figure, and equally lost all chance to set forth the intellectual. How could any one care for a print of this kind, even though the likeness were faithful?

But how wonderful are the resources of art when we can re-establish fine portrait conditions by merely lowering this white sheet to within six inches from the floor. How the figure looms out again; how height and dignity have returned. We have the man triumphing over accessories.

Do not these demonstrations prove that a single pose can be made to interpret a variety of characters simply by a change of accents? Is this not an advance upon the former conception of the meaning and office of the pose? However, we must accept

background and makes for atmosphere. It explains to the mind what the forms of the body mean, thus easing the mind's work and adding to the pleasure of the impression.

Notice in this second drawing how we get an effect of lighting through the one agency of the descriptive line. This line crowning the hat is faint because of the light on it; here it is a little firmer, here it is actually interrupted, at this point it is quite positive, and this lower rim of the hat has a powerful accent of dark. In this wise that hat comes to have roundness. Similar changes in the accents of the outline are to be found in the face, the neck, the hair, the arms, hands, and dress. For no distance does any outline maintain sameness of thickness. Wherever we soften marginal sharpness the light seems to have effect, and wherever we leave it evenly, mechanically hard light is absent. Therefore, we cause all lines to change emphasis at all points, and by doing so consistently we make forms round and give depth to space. The descriptive line is in a sense one form of gradation, and in gradation lighting has its being.

Observe how gradation has been used in this face. We have

Fig. 1.

Fig. 2.

Fig. 3.

the fact that the best thought-out pose will not save the good straight photograph from appearing patchy, disjointed, and unemotional, for which reason we must treat the figure and the background by working on the plate. These outlines, formed by the dark clothes against the white background, create what you call marginal sharpness. Always misused in such cases by straight photography, it becomes a defect, for it cuts the figure loose from the background and destroys the atmospheric connections. In fact, marginal sharpness uncontrolled is the greatest enemy lighting has.

See this outline drawing of a young woman (Fig. 1). Each line is assertive; each enslaves the eye. Wherever our gaze strikes such a line we are impelled to follow it, much as a telegraphic message follows its wire. A line of this sort divides the surface; under no conditions will it unite what is on either side of it, and by its use only flatness can result. Since this is true, how can we expect to give the appearance of body to any human form represented with absolute marginal sharpness? It is necessary that photographers should acquaint themselves with a new factor, the descriptive line. As a help in making objects look round, this line is almost limitless in its resources. It is the greatest friend that lighting has. It fuses the body with the

frontal lighting, the kind that is much in favour. The gradations in this plan of lighting are very subtle, and give opportunity for increased expressiveness in the features, but there is danger that photographers will use too much shading. It frequently happens that, because of this excess of shading, photographed flesh effects have a dangerous tendency to run into a hardness not characteristic of flesh. It sometimes amounts to a porcelain quality, or to a discoloration, as if the flesh in the shaded parts were of a kind dissimilar to that in the lighted sections. We should guard against this with particular care. Notice that gradation is everywhere present in the hat and the dress. Here, too, there is the constant play of shading, and the descriptive contour aids the flow of forms, one into the other.

I want to repeat with emphasis that the trouble with the camera is that it does not record nature as the human eye sees it. First, it records too much, and too confusedly when portraiture is the aim; second, the camera's eye does not see as well as does the human eye that studies. The human eye that studies changes its focus constantly, fixing the mind in turn upon each consecutive part. We then get the descriptive line that takes the place of the camera's marginal sharpness. Nor

does the camera amplify by giving our view of the person, which is a matter of supreme importance in portraiture.

What I have said is not a criticism of your work here in these rooms. There is nothing personal said or intended. I, as an educator, have analysed photography, the most facile method of reproduction the world has ever known. You are all ambitious to make it a perfect tool. Pride, profit, and position are involved. I have tried to lay bare the foundation; elsewhere you have a guide to help you build up your art, and there are also at your disposal processes that will enable you to get all the effects needed in the new creative work. Taking up a photographic plate, I see that the image is recorded through density of film. Now, why should we not add to or lessen these densities at our pleasure? By doing so we utilise what is best in the pose, and then we treat the plate until we have attained those effects I point out as essential in portraiture. When I look at your work I find such high quality, such good photography, that I feel nothing better can be done along those lines. It remains to achieve pictorial completeness. I believe with you that some of the needful effects can be in a measure secured by straight photography, but not in sufficient degree, and never with complete balance.

Why do you hesitate to go a little beyond straight photography? Whether you get density by direct skylight, or by using your fingers in distributing pigment on the plate or employing the reducer skilfully, what can sustain the objection? You will have observed by my work before you here that portraiture is not a copying of nature. The uninformed may not realise how true this is, but you have seen that there was a reason for each touch from beginning to end for each omission,

each accentuation. I do not say that artists consciously employ these reasons in every work, but I know that through study they have acquired a knowledge far exceeding anything that I can put into words in this hour's demonstration. I urge that you all adopt the habit of study, patiently experimenting, and the course of time you will become familiar with the reasons why you will work intuitively. Let us always keep before our minds the truth that good, straight photography will give the likeness, but that the portrait grows out of elaboration. I refrain from showing you more than can well be used in your work for the coming year. There are, however, problems for us to solve so limitless in variety that we may well consider the expediency of organising in order to help onward education among us. Progressively arranged lessons would certainly help in the practice of our art. We must get on higher ground, and above commercial influences, for we must realise that our photography, once launched in an endowed institution of education, will show an undreamed-of realm of invention and creation.

I have unbounded faith in the professional photographer. Holding this belief, for more than a dozen years I have laboured with you to overcome photography's difficulties. I am convinced that photographers may become a greater power for good and for the advancement of art than our art schools can ever hope to be, for the photographer is in daily living touch with every home in our land. His influence is unbounded, and its seriousness should not escape him. No higher ambition can beckon than the one that now urges you onward. Let us all join in advancing a movement that holds so much for the profession and the public. Let us make the advance guard a strong one; let no tarry in the rear.

OTTO WALTER BECK.

## ODOURLESS REAGENTS FOR SULPHIDE TONING.

[The following first account, by Mr. Harry E. Smith, of a process for dispensing with the objectionable sulphide solution in the sepia toning of bromides is communicated to the current issue of the "Journal" of the Royal Photographic Society. The process, which has been provisionally protected, is the subject of some further notes, which the author has been good enough to send us.—Eds. "B.J."]

THE present method of toning black bromide and gas-light prints to a sepia brown colour, often referred to as the "sulphide" process of toning, is open to objections. The most prominent of these seems to be the unpleasant smell of sulphuretted hydrogen given off by the alkaline sulphide solution (sodium sulphide generally), which is used to convert the bleached image into the brown sulphide compound of silver. Another is the liability of this method to give yellowish-brown tones on gas-light papers, and also on bromide prints that are lacking in contrast, a crisp brilliant black bromide print being desirable to start with if the best sepia tones are desired.

I have for some time been trying to find a suitable odourless reagent in place of the alkaline sulphides now used, testing compound salts containing sulphur, which are in themselves odourless, but might be expected to break up in the presence of finely divided silver. The first compounds that I made were thiocarbonates, such as potassium thiocarbonate. I did not, however, meet with much success with these, the impure salts, at all events, having a much more objectionable odour than sodium sulphide. After making a large number of compound thio salts, I have recently found that in the alkaline thiomolybdates we apparently have the desired compounds.

### Substitutes for Sulphide.

Taking ammonium thiomolybdate,  $(\text{NH}_4)_2\text{MoS}_4$ , as a typical specimen of this class, I find that a freshly prepared solution is practically odourless, and that 60 minims or drops (one drachm) of a one per cent. solution of it in one ounce of water, to which

is added five minims of .880 ammonia,  $(\text{NH}_4\text{HO})$ , may be used in place of an alkaline sulphide to tone the bleached silver image.

After toning, the prints must be rinsed, and unless the whites are desired to be of a creamy colour (and I would not recommend that they be left so), the prints should be immersed for about five minutes in a bath of dilute ammonia, five per cent. strength being suitable. This bath renders the clearing of the whites before the final wash (which is all that remains to be done) a short process, twenty minutes in running water being, as a rule, sufficient. A one per cent. solution of the ammonium thiomolybdate may be made up, and, as regards its toning properties, seems to keep fairly well, but if kept for more than a day or so the smell of sulphuretted hydrogen will be noticed, and if this smell is objected to, or, indeed, in any case, I would recommend that a fresh solution be made up from the crystals when required for use. This is very simple, as they are almost instantly soluble in water.

A minim, of course, weighs .91 grains; but, if we assume that a minim equals a grain, and take one grain of ammonium thiomolybdate crystals to two ounces of water (with ten minims or drops of ammonium hydrate), this, though not quite in the above proportion, will be found quite near enough for practical purposes. It is better not to exceed this strength, or with some papers the film may be sufficiently stained to require rather a prolonged final wash. This stain, however, which somewhat resembles that of potassium bichromate, may be cleared with ammonia, or, if persistent, with potassium or sodium metabisulphite.

### A Modified Toning Action.

The toning action of ammonium thiomolybdate solution is apparently that of not only converting the bleached image into the usual silver sulphide compound, but also of depositing in the sulphided image a proportion of sulphide of molybdenum. This deposit of molybdenum sulphide is of great importance, as it enables bromide prints that are too flat in contrast to be satisfactorily toned by the ordinary sulphiding method, to be easily toned to a fine sepia brown. Gas-light prints also take much better tone than the thiomolybdate solution, the tendency to yellowish tones being apparently overcome.

When the black silver image is bleached to silver iodide (as is sometimes done, with, for example, a solution of iodine in potassium iodide), it is advisable to clear the blue iodide of arch from the print with sodium sulphite as usual, as the thiomolybdate bath only partially discharges the blue colour if used for a moderate time.

When the silver image is bleached to chloride, as is sometimes done with potassium bichromate and hydrochloric acid, I do not find that such good tones are obtained as by the use of the usual ferricyanide and bromide bleacher.

### Other Substitutes.

Other thiomolybdates that I have used in place of the ammonium salt are potassium thiomolybdate,  $K_2MoS_4$ , and the double thiomolybdate of copper and ammonium. A saturated solution of this very insoluble salt can be made by heating, and should be used of full strength. While the potassium salt gives good tones, it is not so easily prepared in a pure state as the ammonium salt, and the copper and ammonium salt does not appear to give such good tones. The sodium salt is troublesome to prepare in a pure condition owing to its great solubility. Of other compound salts of a somewhat similar type that I have tried for this purpose (keeping to the same chemical group of metals, viz., the chromium group), I have tried tungsten and uranium to replace the molybdenum in an alkaline thio-salt. The alkaline thiotungstate that I would recommend is ammonium di-thio-oxytungstate,  $(NH_4)_2WS_2O_7$ ; a solution of this salt of the same strength as above recommended for the thiomolybdate giving a good sepia tone. It is better not to use the ammonium hydrate in the thiotungstate toning bath. The thiotungstate, however, does not seem to give such rich tones as the thiomolybdate solution, neither does it compare so well with it in regards freedom from odour in solution.

Replacing the molybdenum with uranium, I have tried potassium thio-uranate. This salt is, however, very insoluble in water, and a saturated solution requires to be used, as in the case of the ammonium and copper double salt previously mentioned. Moreover, it is of little practical use for toning the bleached image.

With regard to chromium, no use can be made in this connection.

### SOME FURTHER NOTES ON ODOURLESS SULPHIDE TONING.

It may, perhaps, be of interest to bromide workers to say that further experiments have enabled us to prove that when working on silver bromide in the laboratory with the thiomolybdate toning solutions as recommended, the bromide is decidedly turned into sulphide, while a sulphide of molybdenum is deposited in or on it. The latter fact I had always proved, and, of course, it was not likely that the black compound remaining could be anything but silver sulphide; but it seems satisfactory to be easily able to prove that it is by treating the residue in the filter with nitric acid, diluting, filtering off the sulphur, and precipitating with hydrochloric acid, the curdy precipitate of silver sulphide being, of course, easily recognised. The presence of sulphur (oxidised by the nitric acid) is further easily shown by precipitating a separate portion of the nitric acid solution with barium nitrate.

Regarding the "red chalk" toning of sulphided sepia bromides with a sulphocyanide gold toning bath, I do not find

tion of salts of this metal having a similar general composition to those mentioned above, as although thiochromites are known, those that have been prepared are, I believe, all insoluble in water, so that they cannot be applied easily to a photographic print. The sulpho-chromates are, of course, a different type of salt, the sulphur in the above-mentioned compounds being replaced by the acid radical group ( $SO_4$ ).

### As to Permanence.

Finally, I think that I may claim that prints toned with the thiomolybdate solution may be regarded as in all respects as permanent as the ordinary sulphide toned print, which has now stood the test of years. The image toned by the thiomolybdate is apparently the silver sulphide compound as usual in sulphide toning. Associated with this we have, however, in this case a proportion of a sulphide of molybdenum, which is no more likely to change than the silver compound under ordinary conditions.

The presence of molybdenum may be proved by treating pure silver bromide with an excess of thiomolybdate solution as prepared for the toning bath, when the silver bromide is seen to change quickly into silver sulphide mixed with molybdenum sulphide. The black precipitate, being washed with water to free it from the thiomolybdate solution, may then be separated into silver sulphide and molybdenum sulphide, by dissolving the latter in a solution of an alkaline sulphide in which silver sulphide is insoluble. If pure potassium sulphide solution be used to dissolve the molybdenum sulphide, the fact may instantly be seen by the colourless solution of potassium sulphide being coloured orange yellow, owing to the formation of thiomolybdate, which without further chemical tests may be recognised by its absorption spectrum. A 1 per cent. solution of ammonium thiomolybdate cuts off all the visible spectrum, except the deepest red, if used in a thickness of solution of two inches. The presence of molybdenum in the solution of potassium sulphide may be confirmed by decomposing the solution with hydrochloric acid, boiling off the sulphuretted hydrogen, and adding a little nitric acid, when the precipitated sulphide again dissolves. On boiling the liquid, and diluting (or neutralising with ammonia hydrate and acidifying with hydrochloric acid), and adding a piece of pure zinc, the solution, when mixed with a strong solution of potassium sulphocyanide, gives the typical crimson coloration (which is dissolved by ether when shaken up with it), indicating the presence of molybdenum.

If prints toned to a sepia colour with the thiomolybdate solution are required to be reduced, perhaps I may say that all the nine reagents that I recommended for reducing ordinary sulphide toned prints ("Photographic Journal," June, 1907, p. 281), will reduce with apparent equal facility those toned with thiomolybdate solution. The cupric chloride and sodium chloride mixture seems to be very suitable, the tones being well preserved.

HARRY E. SMITH.

that this gold bath is satisfactory with thiomolybdate sepia toned prints, the tones being, as a rule, a greenish brown. If the smell of ammonia is objected to in the thiomolybdate toning solution, one or two drops of a saturated solution of potassium metabisulphite may be used instead of the ammonia to each ounce of toning solution made up. This keeps the solution quite odourless, in my experience, but the tone at first is nearly a black or blue-black, though it afterwards turns to a satisfactory brown. Toning solutions with metabisulphite, however, do not keep so well, the action of the metabisulphite being to break up the thiomolybdate. This is, however, of little importance, as I would not recommend that the toning solutions be kept in any case. I have tried this process for intensifying negatives, and find it very suitable, the intensification, owing to the colour of the deposit, as well as to the added molybdenum sulphide, being very considerable. It is probable that suitable thiomolybdates will be put on the market shortly. Some so-called

sulphomolybdates compounds may even now be obtained; and, running short of my own preparations, I got some of these, and at once found that, though no doubt they are what they claim to be, they are not the compounds I have recommended. To start with, these compounds were almost insoluble in water; they could not be called crystalline, and, above all, I could not detect in them any of the dichroic properties (green by reflected, and red by transmitted, light), so typical of the crystals of normal thiomolybdates. These compounds were probably salts

of trisulphomolybdic acid, and were useless in this connection. A sample of ammonium thiomolybdate prepared in my laboratory possesses a very fine dichroic effect. Please do not take, however, that the ammonium salt would be the most suitable thiomolybdate compound to put on the market. As is well known, it often unfortunately happens that the best compound to use in a laboratory is not necessarily the best for a commercial article, as the questions of keeping properties, etc., complicate the matter. HARRY E. SMITH.

## MULTIPLE - COLOUR ILLUMINATION AS AN AID IN PHOTO-MICROGRAPHY.

EVERY photo-micrographer sooner or later meets with a subject of which, owing to its lack of contrast, it seems almost impossible to obtain a really satisfactory and convincing photograph. In my own biological investigations, such subjects have constantly to be photographed, and at one time were the cause of much vexation and many weary hours of labour. For the last three or four years, however, I have adopted a method of multiple-colour illumination, based on the principle suggested by Mr. Julius Rheinberg, which has enabled me to obtain with ease most successful photo-micrographs of these hitherto difficult subjects. From the practical results and experience thus obtained I have no hesitation in recommending this method of illumination to the consideration of all who are interested in photo-micrography.

### Preliminary Arrangements.

I will suppose that the photo-micrographer has a microscope properly equipped with a substage condenser capable of being accurately centred, and having some form of holder to carry patch stops, for producing dark-ground illumination. Also that he has carefully and thoroughly tested his set of patch stops, and knows which of the series produces the best result with a given objective and eyepiece. Comparatively few workers appear to fully realise the vital importance of accurately adjusting the diameter of the patch stop to the aperture of the condenser and objective in obtaining perfect results by dark-ground illumination. Unless the diameter of the patch stop is of suitable size it is impossible to obtain the best results, and I believe this is the chief reason why dark-ground illumination has been comparatively neglected in the practice of photo-micrography. The additional apparatus necessary for the production of multiple-colour illumination is neither costly nor difficult to obtain, and consists of some sheets of different-coloured gelatine, such as red, blue, green, yellow, and clear uncoloured, and some micro-cover-glasses of a size that will fit the patch stop holder of the condenser.

### Making the Coloured Stops.

Having obtained the necessary sheets of gelatine, the next step is to cut from them a series of discs that will fit the patch stop holder, and then punch a hole in the centre of each just a shade smaller than the central discs of the patch stops. Next, another set must be cut out exactly the same size as the central discs of the patch stops, and mounted on full-sized discs of unstained and transparent gelatine, by slightly damping and pressing into position, or moistening with a strong solution of gelatine. Now make another set of marginal discs with central holes, from the transparent sheet of gelatine, and mount on each disc four coloured sectors, the two opposite sectors being of the same colour—say, for instance, two red and two blue, or two red and two green, or two blue and two yellow. Cover the centre openings of these compound coloured discs with circular stops of suitable size made of black paper or thin black card. It will also be as well to make a set of

marginal discs composed of two sectors, one blue and the other red, or one green and one blue. I have found it of great convenience, when by experiment the most useful combination of colours has been determined, to mount the marginal and central stops up together between two micro-cover-glasses, as by this means they are not only protected from scratches and finger-marks, but they will keep flat and in proper register.

### Adjusting the Coloured Illumination.

The stops made, the next thing is to put them into use. Set up the microscope, and, using, say, a 1 in. objective, focus a slide of potato starch grains or some foraminifera. Centre the substage condenser carefully and obtain critical lighting, and then, by means of the paralleliser, even illumination. Working with low powers such as the 1 in. or 2 in. objectives, the top lens of the substage condenser should be removed before the condenser is focussed.

Having focussed the object and obtained even illumination, open the iris diaphragm of the substage condenser to its fullest, and insert in the stop-holder a red marginal and a blue central disc. On looking through the microscope, the object will now be seen to stand out brilliantly illuminated and of a perfect red colour against a deep blue background, the contrast being most striking. Now, keeping the same object on the stage, experiment with the various coloured discs, keeping in mind that the central discs, which are responsible for the colour of the background, should always be of a darker tint than the marginal discs.

If the photo-micrographer is a really keen worker, it will well repay him for the trouble to make for himself a set of standard chart for reference, which will show at a glance the result he can obtain by the combination of the various coloured central and marginal discs. This he can easily accomplish by taking a series of photo-micrographs of the same object illuminated with different combinations of the coloured discs. From these negatives he can make a set of prints, mount them on a card, and mark under each the colour of the central and marginal disc used.

### Compound Coloured Discs.

Having experimented with the single-coloured discs, try the effect of one of the multi-coloured discs made up of four sectors, but this time using as the object a strand of silk mounted in Canada balsam, or a section of the stem of a pine unstained. The result will be a most striking and delightful blending of colours. For instance, if a composite disc of red and blue sectors has been used, in conjunction with an unstained section of a pine stem, all the horizontal fibres will appear blue, and all the vertical fibres red.

Now, using the whole condenser, and  $\frac{1}{4}$  in. or  $\frac{1}{2}$  in. objective, arrange a slide of diatoms having fairly coarse markings upon the stage of the microscope, and insert in the stop-holder a ruby-red central disc and a malachite-green marginal disc. The colour of the green disc is rather important; it can

made by pouring a small quantity of a solution of collodion dissolved in equal parts of alcohol and ether, to which the stain has been added, over a sheet of clear gelatine, or over the ordinary green gelatine, and allowing it to dry, when it should be of a blue-green colour. On looking through the microscope the whole field or background will appear green, which is due to the aperture of the objective being sufficiently great to admit a cone of light much wider than that proceeding from the central red disc alone, the consequent excess of green light having the effect of completely swamping the weaker red light.

Watching closely, and working slowly, gradually close the iris diaphragm of the condenser so as to reduce the cone of light and partially cut out the excess of green. If this is done carefully, the background will be seen to gradually change colour until a point is reached when it will appear a neutral or almost white tint. The diatom should now stand

out from this pale background in brilliant hues of red and green, the ridges on the frustule green, while the depressions and holes show red. This selective colouring is due to the ridges on the frustule of the diatom catching the oblique green rays, while the transparent parts and perforations receive only a very small proportion of these oblique rays, but pass an excess of the red rays forming the centre of the illuminating cone. I consider this a very useful means of determining the structure of diatoms, while for the photo-micrographic demonstration of their structure it is of the greatest assistance. In taking photo-micrographs by this method of multiple-colour illumination, as in all photo-micrographic work, backed isochromatic plates should be used.

If it is given a thorough and fair trial, I am convinced that the photo-micrographer will find multiple-colour illumination of very great service to him in his work.

F. MARTIN DUNCAN, F.R.P.S.

## FINE FOCUSING METHODS—OLD AND NEW.

In ordinary field work it is easy to obtain sufficiently accurate focussing on an ordinary ground-glass screen without adventitious aids. For the pencils of light from points at practically infinite distance away diverge rapidly from their convergence points in the focal plane of the lens, and the very small displacement of the screen necessary to put the image badly out of focus is favourable to accuracy of adjustment.

But in the photography of objects close to the camera (*e.g.*, diagrams for lantern slides, delicate apparatus and so forth) the depth of focus is much increased; the ray pencils from each point of the object diverge but slowly from the point foci in the image plane. Consequently the focussing-screen can be moved through appreciable distances without perceptibly affecting the apparent eye-judged sharpness of the image on the screen, and doubt exists as to its precise setting. In such cases the employment of a magnifying-glass is helpful; not that the glass can contribute much in the way of showing up fine detail on the ground-glass surface, but it enables one to locate the position of maximum crispness of outline and freedom from nebulosity in the gross image with more certainty than can be attained without its aid.

The ordinary ground-glass screen, though fortified with a magnifier, is, however, quite inadequate when the most perfect focussing of very delicate detail is in question, for the finer detail of the image is broken up and confused by the scattering action of the roughly ground surface. In such cases recourse is frequently had to screens with a finer grain and with greater transparency than can be secured by grinding glass. A description of some such substitutes for ground glass appeared in the *BRITISH JOURNAL* for March 30, 1906. The aim, of course, is to obtain a screen of just so much, and no more, optical irregularity of surface as will prevent an image formed by the lens in front of the screen from being seen through it. Though such screens display a far higher order of detail in the image than do ground-glass screens, yet they labour under the disadvantage that, with the exception of the small portion of the image which happens to lie in the neighbourhood of the line joining the eye with the optical centre of the lens, the image as a whole is much dimmer than in the case of the coarser ground-glass screens, and therefore the eyes must be very carefully shielded from extraneous light, in order to permit of the composition and proper centring of the picture on the screen.

### A Fine Focussing Screen.

For some time I have made use, with good results, of a novel screen of this class prepared by the following procedure:

A plate which has been exposed in the camera to a uniformly lighted sheet of paper is developed, fixed, and then placed in a bath of hydrogen peroxide acidulated with sulphuric acid. The bath is warmed to a temperature of about 20 deg. C. In a short time the hydrogen peroxide removes the developed silver and concomitantly some of the gelatine in which the silver was embedded, leaving the remaining gelatine in a very faintly opalescent condition. The plate is now washed, treated with Farmer's reducer if it still looks brown, and dried. A screen so made has just enough optical irregularity to prevent the image being viewed through it, but not enough to militate against the presentation of very fine detail in the focussed image. I must confess that I sometimes failed to get a good screen by this process even when observing, so far as I was aware, the same conditions that in previous trials had led to satisfactory results. This uncertainty or "trickiness" in manufacture is to be regretted, for of all the many screens I have experimented with none seemed to give such perfect detail rendering in the image as these gelatine screens.

### The Transparent Patch Method.

A much favoured device for fine focussing is a ground-glass screen of which a portion has been rendered quite transparent. The major translucent portion of the screen serves the purpose of centring and composing the picture, and the final focussing is done whilst observing the image through the transparent portion of the screen with a magnifier. Local transparency is secured by cementing on the ground-glass by means of Canada balsam a microscope cover-glass. Pencil lines drawn on the screen before balsaming are used as an object for the preliminary setting of the magnifier. When one of these locally transparent screens is used very great care must be devoted to the setting of the magnifier. It is carefully focussed through the screen on the pencil marks and set accordingly. (It is, I think, questionable whether lines which have been pencilled on ground glass form the best conceivable objects for determining the setting of the magnifier, for the separate carbon patches of which the lines are built up are always somewhat vague and nebulous as to outline.) Now, it is assumed that if the image is seen sharply through the magnifier so adjusted, then the image must be in the plane of the front surface of the focussing screen (*i.e.*, in the plane of the pencil marks). But it seems to me that this method of attacking the problem of securing critical focus is open to serious objections. On account of the accommodative power of the eye, the magnified image seen through the transparent portion of the screen may

appear quite sharp, even when it is not in the same plane as the pencil marks.

#### High-Power Magnifier Accommodation.

Take the case of a person of normal vision who can accommodate for any distance from "infinity" to a near-point of, say, eight inches. If such a person use a magnifier of one-inch focal length, he will in virtue of accommodation be able to see a perfectly sharply defined virtual image of any object (or primary image) distant from the magnifier either one inch, eight-ninths of an inch, or any distance intermediate between these values. In the preliminary setting of the magnifier his eye may be unaccommodated—i.e., the magnifier is set one inch from the plane of the pencil marks. Suppose this to be the case, then when racking out the focussing screen for the purpose of focussing the image the observer is very apt to accommodate the eye without consciousness of the fact, and stop the racking out when the movement of the screen is such that the image (assuming, for the sake of argument, full accommodation) is only eight-ninths of an inch from the magnifier, and therefore one-ninth of an inch behind the plane of the front surface of the screen. (The figures here given are merely illustrative. They are calculated on the assumption that the magnifying lens is ideally thin, and that the eye is in contact with it.) It should be noted that errors in focussing due to the instability of accommodation vary in possible magnitude with the focal length of the magnifier used. Thus with a magnifier of half-inch focal length, the maximum possible error in setting the screen would be reduced from one-ninth of an inch to one thirty-fourth of an inch. Hence it would appear to be advisable to use a magnifier of higher power than those usually sold.

Of course, if one could concentrate one's attention simultaneously on the pencil lines and on the image, such errors in focussing as I have suggested would be impossible; but as Dr. Wells in one of his optical essays puts it, "We are by our present constitution capable of attending accurately to only one thing at a time." The pencil marks are opaque; the image cannot be seen through them and superposed on them. To see the image distinctly direct vision must be diverted—slightly, perhaps, but yet diverted—from the pencil marks, and during this diversion of the line of fixation slight changes of accommodation may take place in the eye without our cognisance.

On account of the uncertainty arising from unconscious accommodation changes to the eye. I have of late quite discarded the method of fine focussing just described, and place my reliance on a parallax method in which accommodative changes to the eye are impotent to vitiate the results.

#### How to Avoid Accommodation.

The screen used is a plate of glass fairly heavily ground all over (with a view to a bright general image) with the exception of a small circular central spot, which is left transparent. Such a screen is made in a few minutes by sticking a small washe on the centre of the plate and grinding round this with carborundum powder, using as a muller a small piece of flat glass to which a slab of wood has been stuck to act as a handle. A small strip of tinfoil cut with a razor is stuck across the transparent portion of the screen. On the unground surface of the glass, just over the region of the transparent disc, a small adjustable magnifier of about half-inch focal length is permanently fixed. (The magnifier actually used was constructed from a cheap linen tester.) The magnifier is focussed on the edge of the tinfoil slip and set. It is not necessary to bestow any especial care on this adjustment. The screen is now racked until there is no apparent relative movement (parallax) between the edge of the slip and any selected portion of the image seen through the magnifier when the eye is moved laterally across the field of view of the magnifier. This being the case, the lens image must of necessity lie precisely in the plane of the front surface of the screen. The function of the magnifier here, it will be noticed, is not to aid the attainment of that very uncertain condition the exact position of clearest visualisation of fine detail in the image, but simply to magnify a displacement. Hence there can be no complications arising from unavoidable accommodative changes in the eye.

The delicacy of this method of focussing—virtually a "null method"—is quite surprising; the most insignificant rotation of the focussing pinion from the position of zero parallax produces an easily perceptible relative displacement of the fiducial mark and any selected image detail. I can confidently recommend those who have met with difficulties in fine focussing to give the parallax method a trial.

DOUGLAS CARNEGIE.

## ALLEGED ANTICIPATIONS OF THE WARNER-POWRIE PROCESS

SOME indication of the interest awakened by the Warner-Powrie process is afforded by the publication in the German journal "Der Photograph" of the heated protestations of a Dr. Mebes, apparently the editor of our contemporary, that the process cannot be patented in Germany. Dr. Mebes claims to be doing the photographic trade of his country a good turn by his alleged proof that the American screen-plate process has no features which entitle it to patent protection in Germany. Dr. Mebes writes as "ein gelehrter Mensch, der kennt Alles," and hence it seems a pity that he does not inform his countrymen of the patent granted to Dr. Powrie by the American Patent Office, the controllers of which are equally as strict, if not stricter, than is the German "Patentamt" in their examination of an inventor's claims. Dr. Mebes cites the French and English patent, but he appears to be ignorant of the date and number of the American patent. If he looks in the U.S. General Index of Patents for 1905 he will see that the entry under Powrie is misplaced in the alphabetical order. Can it be that in his haste to disparage the process, Dr. Mebes has missed the entry in the register? It is not a very charitable suggestion, but nevertheless the most plausible we can think of. Probably the German photographic trade will begin to feel grateful to Dr. Mebes when he points out this entry in the index.

As Dr. Mebes may not do this, it may be well for us to refer to his criticisms of the Warner-Powrie process. They cite a patent of Brasseur (No. 571,314 of U.S. patents), which describes the use of a screen with opaque and transparent bands (the former double the width of the latter), in conjunction with three mono-chromatic light filters, for making a banded negative in three separate exposures. The patent does not refer to a colour screen-plate or to the printing of a three-banded filter-plate from such a double-band screen, and the use of such a "double-band" screen is not mentioned as an essential item in the claims of the Powrie British specification or fails to see the relevance of Dr. Mebes' citation.

Similarly Dr. Mebes cites the MacDonough British Patent, No. 5,597 of 1892, to show the Powrie patent cannot obtain protection for colour screen-plates in general, that is, combinations of filter screen and emulsion, which, of course, it does not, but only for a particular form of screen-plate and a particular method of producing it. Dr. Mebes must be very imperfectly acquainted with the claim in the Powrie English specification or he would see that in citing these alleged anticipations—which, by the way, are not the best he could cite—he is ploughing the sands.

Lastly, he comes to the claim in the Powrie specification for a plate of three coloured portions, all contiguous and forming a full

filter surface, as an anticipation of which he quotes the classical French patent of Du Hauron (No. 83,061 of 1868). It cannot require much knowledge of patent distinctions to perceive that a previous description which says not one word on the method of securing contiguity of all the colours and flatness of the finished filter is perhaps not the best publication to bring up as an anticipation. Du Hauron, as everyone knows, originated a great idea in this patent, but that he dropped one hint as to the methods of forming the filter plates which are under discussion in the Powrie patent is flatly contradicted by the specification from which Dr. Mebes has taken extracts. In short, Dr. Mebes' criticisms amount to this: He cites Brasseur and MacDonough to invalidate claims in the Powrie patent which do not exist; and when he quotes Du Hauron as anticipating an actual claim in the process, behold Du Hauron says nothing on the essential points.

We would not think it necessary to deal with the historical fallacies of Dr. Mebes did they not afford a nice illustration of the blunders which the hurried writer can easily make. In his case it does not matter much to anybody, but we are thinking of one or two instances which have come before us quite recently in which the disregard, through ignorance, of the rights subsisting in certain patent had involved those who could ill afford it in expensive litigation. Dr. Mebes' efforts, no doubt, arise from the most patriotic motives, but his countrymen, it is to be hoped, are too astute business men to accept them as the word of a competent authority.

## THE SOCIETY OF COLOUR PHOTOGRAPHERS.

### ANNUAL MEETING.

THE annual general meeting of the Society of Colour Photographers was held on Thursday, October 17, at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY, where at the present time the exhibition of the Society is being held. Amongst those present were:—A. J. Newton (London), A. W. Everest (Hampstead), F. T. Hollyer (Kensington), George E. Brown (London), H. Snowden Ward (London), J. Wall (London), F. S. Poole (Godalming), A. Lander (Canterbury), E. D. Doncaster (Surbiton), C. W. Madden (Highbury), E. Weinberg (London), Sidney L. Young (London), E. W. Burchard (Bicester), W. Fischer Keep (Putney), C. Welborne Piper (Blackheath), Dr. H. Hutchinson (Lowestoft), Paul Corder (London), and Henry J. Comley (Stroud).

Mr. A. J. Newton was voted to the chair. Arising out of the Secretary's report (appended) some discussion took place as to the more rapid circulation of the portfolio of prints and the cases of free-colour transparencies. It was decided to restrict the time during which each member should hold the portfolio to three clear days. Arising out of complaints that the portfolio occasionally remained longer than its scheduled time with members, it was pointed out that in the case of members who were away on their holidays the portfolio might remain unexamined until their return. On the suggestion of Mr. E. D. Doncaster the present automatic rotation system to be replaced by one under which each member of the Society is notified by the secretary a few days in advance that the portfolio is due to reach him, and will be sent on or his replying that he is in readiness to receive it, and send it on to another member.

The officers for the ensuing year were re-elected, namely:—Secretary and treasurer, Henry J. Comley; committee, George E. Brown, T. Hollyer, A. J. Newton and E. J. Wall.

Messrs. E. D. Doncaster and A. W. Everest were appointed auditors. Mr. G. E. Brown said that it had been a great pleasure to co-operate with the society in holding the exhibition, yet he regretted to say that the time of year was in many respects—the months of September, October and November—so fully occupied by both publishing and editorial staff of the BRITISH JOURNAL that he did not see that it was possible to offer the exhibition rooms another year during these months. After some discussion it was decided to hold an exhibition in the earlier part of the year, probably in May or June of 1908.

The following is the text of the Secretary's report:—

Ladies and Gentlemen,—It is with a great amount of pleasure that I present to you the first annual report of the Society of Colour Photographers. The first year in the history of a society of this kind cannot be expected to be anything more than a period of experi-

ment in organisation and preparation for the future. I do not claim that anything greater can be said of the Society, but the success which has attended it during its one year of existence has been indeed very encouraging.

Commencing on October 16, 1906, with a nucleus of eleven members, we now have a membership of seventy-three, of whom fifty are working members. The remainder are ladies and gentlemen who have joined us in order that they may show their sympathy with the aims of the society, and at the same time keep themselves informed of the latest advances in colour work.

Our members are very widely scattered; twenty-five live within the London postal area, and while the majority of the remainder are distributed all over England and Scotland, we have members in America, the Transvaal, India, Belgium, Switzerland and Italy; and I am convinced that with the continued interest and co-operation of the present members, the society may soon largely increase its numbers and claim a position among the most important societies in the photographic world.

Very few photographic societies are able to hold an exhibition during the first year of their existence. In this particular we have probably created a record, and it is encouraging to know that the exhibition has been visited by a far larger number of people than was anticipated, and has received the most favourable comments from all sections of the press.

Very few young societies have received so much encouraging recognition from the press both photographic and lay; on numerous occasions during the year paragraphs concerning us have appeared in the leading London dailies, and these have been copied by the foreign and colonial press until in the brief space of twelve months, the Society of Colour Photographers has become known all over the world. Special mention must be made of the great assistance given to the society by the editor and proprietors of THE BRITISH JOURNAL OF PHOTOGRAPHY, who have not only on various occasions devoted a large amount of space in their JOURNAL to notices and correspondence relating to the society, but have always very kindly placed a room at our disposal for the meetings of members and committee. They also very generously offered to house our exhibition without charge on condition that admission to the exhibition should be free. This offer the committee very readily accepted. The "Colour Photography" supplement of THE BRITISH JOURNAL has been a great boon to the members of our Society, and to colour workers in general. All this kind assistance on the part of those connected with THE BRITISH JOURNAL OF PHOTOGRAPHY, has, of course, been a great saving of the funds of the Society, and I am sure that our sincerest thanks are due to them.

Reviewing the year's work one cannot help feeling that more might have been accomplished, but there has been a great amount of satisfaction in the knowledge of the fact that the work done has been foundation work, and although it leaves room for great improvement in succeeding years, the past year's work has probably decided the possibilities of the future of the society.

Taking the activities of the Society in their published order, (a) Four portfolios of prints and two cases of transparencies were put into circulation, and these, together with the hints and criticisms upon the work which accumulated as they passed from member to member, have proved most interesting and instructive.

The great difficulty in connection with the circulation of the portfolios has been to get together sufficient work to make interesting collections, and it will also be readily seen that owing to the fact that five days have been allowed to each member for the inspection of the work in the folio, although a number of folios have been in circulation, many of the members have only had the opportunity of receiving one. The time allowed for the inspection of the portfolios should, I think, be reduced to three clear days; in this way all the folios would pass into the hands of all the members in a little over a year.

(b). A number of members have taken advantage of the privilege offered by the society, by which they may correspond with the secretary upon matters of difficulty experienced in their work. It will be remembered that a number of gentlemen placed themselves at the disposal of the society for the purpose of answering technical questions of this kind through the medium of the secretary, but the questions asked have generally been of such an elementary character that the secretary has been able to give the information without

referring the matter to experts, and has thus avoided excessive correspondence.

(c). Referring to the exhibition which is now in progress, it must give you all a great amount of satisfaction to know that it is such a great success; all the popular processes are well represented, and the quality of the exhibits is, generally speaking, very satisfactory. The combined exhibits of prints and transparencies are quite the best collection of colour work that has ever been brought together. We have to congratulate ourselves upon having the honour of introducing to the world the extremely interesting and successful "Warner-Powrie" process, which is probably destined to rapidly come into public favour as a thoroughly practical and commercial process of colour-photography.

The success of the exhibition is largely due to the interest and untiring efforts of Mr. G. E. Brown, the Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*, who so kindly undertook the onerous duties of arranging and cataloguing the exhibits. He also at a very great sacrifice of valuable time assisted in the clerical work necessary in getting the collection together; and a number of the most interesting items in the catalogue, including the "Warner-Powrie" exhibit, is the result of Mr. Brown's efforts, which cannot be too highly appreciated.

The future of the Society will largely depend upon the interest which the present members take in its welfare. The first great need is for the working members to send in sufficient new examples of their work to fill at least three new portfolios and three transparency cases; these, with the portfolios already in hand, would give us a good start for the year, and would enable the secretary to keep alive the interest of those who have not yet taken up practical colour work, and to encourage them to turn their attention in that direction.

It is interesting to mention that one or two of our members are working out original ideas for the perfecting of printing methods; others are experimenting in the direction of improved methods of negative making; and at least one is working upon a process of direct colour photography. This society should be in a position to encourage workers who are engaged in original research, and for this purpose gifts of scientific apparatus would be very welcome. This apparatus would be the property of the Society, but would be available for the use of members applying for same.

I sincerely hope that you will all have the future welfare of the Society at heart, that you will encourage others to join us and take up colour-photography, for with an increased membership in London we would soon be able to have a programme of members' meetings, which would be a means of greatly enhancing the usefulness of the Society.

HENRY J. COMLEY,

October 17, 1907.

Hon. Secretary and Treasurer.

#### SOME ESSENTIALS TO COMMERCIAL SUCCESS IN PORTRAIT PHOTOGRAPHY.

WHILST many photographers are complaining of the badness of the times, there are many others who have discovered that business in quantity is to be done, but on business lines which call for more application and discretion than were sufficient a few years ago. The following short paper, read before an American convention by W. J. Hillman, of Richland Centre, emphasises some of the ways in which the photographer may find on self-analysis that his methods may benefit by revision:—

Be very careful in making your sittings. See to it that you have the very best that you can produce in the way of negatives. Do not let a plate or two stand in the way of your success, but know yourself that you have the very best negative that can be made before the customer leaves the studio; for with good negatives and proper care in the printing and finishing you are sure to turn out a pleasing portrait. I believe that it pays to put in honest and conscientious work all along the line. Our customers will, in time, recognise our efforts to please them, and, knowing our integrity, will be more inclined to give us their patronage rather than to pass it to those who are known to be careless and indifferent as to the quality of their work.

#### QUALITY TELLS.

Let us be clean and painstaking in finishing our work, remembering that a clean, well-finished picture is a credit to its maker and a

travelling advertisement for more patronage, while a dirty, slovenly piece of work is an abomination, unworthy of the efforts of the producer; and, while also a travelling advertisement, it is that keeps away trade rather than that it should bring business to the one who is known to have sent it on its rounds.

Let your pictures have a clean, crisp appearance as they go to the hands of your patrons, and by placing a small envelope of unfumed sachet powder within the package, with your advertisement neatly printed thereon, thanking the patron for the favour of order, it will give a dainty effect and prove very pleasing to the customer.

#### WORK TO TIME.

The confidence of the public is your "winning card," and is worth much to you in your business. Do all you can to gain and retain this confidence, for it means success. Finish your pictures promptly and on time, according to agreement. Do not agree to have pictures done at a certain time and then fail to deliver them (making excuses that the patron will consider only as such), for how can you keep the confidence of your patrons while disappointing them, and will they think of you as a business man if you treat them in this manner? Again, how humiliating to you if you have to make kinds of excuses for not finishing their work when promised.

Soon you will have lost your reputation for reliability and promptness, and your competitor over the way has gained a customer through your negligence. Be prompt if you would succeed. Let it be understood from the start that you are a man among men, not a "cheap John." Let the people understand that you are doing the very best work at reasonable prices, and that your products are fully worth the price that you ask for them; that you are in the business for your health, nor in competition with the cheap man in the country, but to live as the people live about you, and gain a competency for old age. Charge prices that will pay your expenses and keep you honest and your name and credit a reproach, leaving a goodly amount for a bank account. Less than this means failure, and, in the end, with credit gone, you are classed with the disreputables and the unsuccessfuls.

#### THE BUSINESS SYSTEM.

Study the cost of your products and see if they can be produced for the prices that you are asking. Remember, you are to be honest with yourself and those who are dependent upon you as well as with the persons on the other side of the transaction. Many photographers figure only the cost of plates, paper, cards, and chemicals, and charge accordingly, thinking that all receipts above these expenditures are "profit," and that their "profits" are large. If you would add the interest on money invested (which is a perfectly legitimate item), the rent of their studios, the cost of fuel, tax, light, insurance, help (if any is employed), repairs to instrument, furniture, etc., and occasionally the addition of a new article of furniture or a new and improved instrument; in fact, all necessary expenses connected with the conducting of the business, and not getting a reasonable salary for the proprietor (whose time, labour, skill, and energy ought to be worth as much as those of men engaged in other professions), they might discover that business was done at a loss, and unless prices were raised to meet the discrepancy, they must close up and retire in a short time.

PROFESSIONAL AUTOCHROME PORTRAITURE.—Mr. Abernethy, High Street, Belfast, so we read in the "Belfast News Letter," announced his intention of undertaking portraits in natural colour on the Lumière Autochrome plates. Professional photographers everywhere will doubtless keep themselves alert to the opportunity of securing some good local advertisement, even if the new department does not bring them a remunerative number of orders.

AUTOCHROMES AT MESSRS. GRIFFIN'S.—Messrs. John J. Griffin & Sons, Limited, write:—"We have secured some exceedingly interesting specimens on the Autochrome plates, produced by an expert at the College, which we have on view in our exhibition room. The photographs are particularly interesting as being the first cases, as we know, where Autochrome plates have been applied to photography. The rendering is extremely fine in the case of photographs of the tongue and lung, the same being taken direct. The transparencies will be shown to visitors."

## ROTHERHAM PHOTOGRAPHIC SOCIETY.

ASS G.—Best Boards of Exhibits.—Silver medal: 228-235, Miss  
tson; bronze medal, 434-442, A. S. Pye; 260-278, W. R. Britton.  
set awarded a bronze medal.

TE SCREEN PLATES.—No. 22,228. Improvements in the manufacture of photographic colour screen plates. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

book or album; but the invention can be embodied in single sheets as well as in a complete book. Upon this page are secured sheets B, preferably of heavy paper, each of the sheets being of the form shown in Fig. 2, the same comprising a central rectangular blank of the size and shape of the picture or other object which it is

desired to mount upon the page and each being provided at its four corners with diagonally extending flaps *b*. Before the sheet *B* is mounted upon the page *A* each of the flaps *b* is folded along the line joining it to the rectangular blank *B*—i.e., along the dotted line *b*<sup>1</sup>, Fig. 2, in front of the blank *B*, so as to form a diagonally disposed corner strip, as shown in Fig. 1. The end of the flap *b*<sup>1</sup> is folded along the dotted line *b*<sup>2</sup>, behind the body of the blank *B*, and pasted or otherwise secured in place. At the upper right-hand corner of Fig. 2 one of the flaps is shown folded into position, and the portion of it which lies behind the body of the blank *B* is indicated by dotted lines.

When it is desired to mount a picture the corners of the sheet are placed under the edges of the flaps *b*. As a modification of the form illustrated at the left-hand side of Fig. 1, sheets are provided, as shown at the right-hand side, the body of each mounting sheet being made in the form of a Greek cross and the flaps *b* being provided at each of the eight corners of the cross, as illustrated in Fig. 3, the same being folded into place, as already set forth. By these means a mounting is secured in which a picture can be held, either in a vertical or horizontal position as desired. Charles Frederick Engstrom, 552, Wabash Avenue, Chicago, U.S.A.

The following complete specifications are open to public inspection before acceptance, under the Patents Act, 1901:—

APPARATUS.—No. 18,399. Photographic apparatus. Seele.

CINEMATOPGRAPHS.—No. 20,863. Cinematograph apparatus for continuous taking and projection by means of photographic plates. Fauconnet.

### New Trade Names.

IMPERIAL.—No. 293,654. Plates and films included in Class I, prepared for photographic purposes. The Imperial Dry Plate Company, Ltd., Ashford Road, Cricklewood, London, N.W., manufacturers of photographic materials. June 11, 1907.

SPEEDY.—No. 294,456. Photographic Dry Plates. Wellington and Ward, The Elms, Shenley Road, Elstree, Herts, photographic material manufacturers. July 9, 1907.

TARGOT.—No. 294,912. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Joshua Rea and Sons, Collingwood Street Oil Works, Collingwood Street, Liverpool, Lancs, oil and paint manufacturers. July 27, 1907.

KOH-I-NOOR.—No. 295,646. Sensitised photographic papers. Photochemische Fabrik Roland Risse, Gesellschaft mit Beschränkter Haftung, 4, Weibachstrasse, Flörsheim-on-the-Main, Germany, manufacturers. August 19, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Position of the Lens in Portraiture.

As a general rule (writes Mr. A. J. Anderson, in an article in "The Amateur Photographer," of October 22, on "Some Principles of Portrait Work," which we emphatically commend to the study of every professional photographer), the lens should be placed level with the sitter's eyes, and exceptions from this rule should be made with a definite purpose. In some few cases a station point that is slightly above the level of the eyes will be found to give a more pleasant rendering of the features, and a sympathetic operator will always be kind to his victim—but in such a case I think that the subject should be shown seated—in other cases a lower station point will be found to give a delightfully saucy rendering of a saucy face. However, as a rule, the higher station point will prove unsatisfactory, for the simple reason that pictures are seldom hung below the line of sight, and a portrait that is placed on a table is generally stood so that it is at right angles with the line of sight; the lower station point is more often satisfactory, but there is always a risk in giving an extra tilt to a nose which is already tip-tilted by nature.

### A Flashlight Stand.

An ordinary folding metal music stand (writes a club secretary in "Focus") is obtained (nearly every household possesses one), the

top part is taken out at the place where the height is regulated, in its place is put a piece of iron rod of the same thickness, about 4ft. long. Then a piece of board is obtained, about 6in. by 3ft. a hole is made in the centre of this, so as to wedge tightly on the end of the iron rod at right angles, or the end of the iron rod can be screwed so as to screw into the hole in the board. The flash powder can then be flashed on this board, or, better still, a piece of cotton wadding is first placed on the board, and the flash powder in this, the cotton wadding is then ignited with a taper, which ignites the powder in about two seconds; this gives the operator time to get out of the way, thus doing away with the cane walking-stick. This stand, as will be seen, can be regulated to any height, and can be folded up in a small space when it has to be carried or put away.

## New Books.

"La Photographie des Couleurs et les Plaques Autochromes." By E. Wallon. Paris: Gautier-Villars. 1 fr. 50.

It is a pleasure to come across an able writer like M. Wallon writing dispassionately of the Autochrome process. His 40-page monograph reviews the principles upon which the one-plate processes of colour photography rest, and incidentally traces the development of the grain method from the first suggestion of Ducos du Hauron. M. Wallon's experience with the Autochrome plates described without ostentation, amounts to this—that any departure from MM. Lumière's precise directions is inadvisable, a conclusion which, however, cannot be said to have been confirmed in its respects by workers in this country.

"Aide Mémoire de Photographie pour 1907." By C. Fabre. Paris: Gautier-Villars. 1 fr. 75 c.

M. Fabre's annual précis of photographic progress, of which the present volume is the 32nd issue, resembles its predecessors in general arrangement, and supplies a conveniently arranged abstract of the principal technical advances of the year. It contains also much information as to photographic societies in France and other countries, a list of photographic books published during 1906, and particulars of the French and foreign photographic press. The latter, in some respects, call for revision.

"La Reproduction Photographique des Couleurs." By H. Calme and L. P. Clerc. Pp. 132. Paris: Office of "Procédé." 6 francs.

This is a compact manual of three-colour practice issued from the office of "La Procédé," in Paris. It is not to be imagined, from the fact that it forms No. 12 of the "Bibliothèque Photomécanique," that the book deals exclusively with three-colour as applied to photoengraving: fully one-half the text applies equally to three-colour photography of all kinds. Thus we have an historical introduction and a full explanation of the nature of light and colour, and of the principle on which three-colour photography depends. Other sections deal exclusively with "Procédés Photochimiques," and "Synthèse Optique." The first includes a working description of all the usual subtractive methods, imbibition, carbon, pinatype, etc., and the last all the synthetical, as triple projection and the chromoscope, describing the new Autochrome and Omnicolour plates. The remainder of the book deals in the first part with everything concerning the making of colour negatives, and in the second with photomechanical work, especially in relation to the printing in and the use of the cross line screen. The book has half a dozen indifferent coloured supplements, but is well illustrated with diagrams in the text.

PLATINOCHROM.—Messrs. Sichel write that they are informed that the new "Platinochrom factory is now completed, and that they will be in a position to resume deliveries of this paper in about fourteen days."

AUTOCHROME FILTERS.—According to Dr. Harberrisser in the "Chemiker Zeitung," very good results are obtainable on the Autochrome plates by the use of a filter obtained by staining gelatin glass with a solution of 9 parts of "rapid filter yellow" and 1 part filter red (Hoechst). The tint should correspond at the most to that of a medium yellow screen. Dr. Hauberrisser suggests that the above formula may be employed if the correct Lumière filter is not obtainable.

## Dew Apparatus, &c.

The "Ensign" Cover-Glass Cleaning Frame. Made by Houghtons Limited, 88/89, High Holborn, London, W.C.

For lightening the labour of lantern-slide binding we can recommend this little piece of apparatus of Messrs. Houghton's, which makes short work of the preparation of the cover glass. The

cleaning frame is of the type familiar to wet collodion workers, and will be endorsed by them as the most suitable kind for the polishing of plates of small size. It consists of a solid block covered with cloth and recessed to just sufficient depth to accommodate the thin lantern-slide cover-glass. The cleaning frame is sent out complete with a couple of screws for securing it firmly to the table top, and costs only one shilling. It should last the slide-worker a lifetime, save him many broken cover-glasses, a goodly proportion of time, and probably some finger-cuts.

Clarkson's Dry-Mounting Block. Sold by F. C. Clarkson, Colchester.

This piece of apparatus consists of a metal plate, conveniently mounted on wood and provided with a thermometer to indicate its temperature. It thus serves as a ready means of securing the adhesion of prints by aid of dry-mounting tissue, and can be got ready for use in a few moments over a gas stove or spirit lamp, or in an oven. The block is made about 7in. x 5in. in size, and may be used for prints of larger size than itself by being kept in motion while applying hot pressure. The block is offered in conjunction with the dry-mounting tissue of Mr. Clarkson, which is supplied for use at the low temperature of 60 deg. C., and affords excellent adherence in our experience of it. A piece of the tissue slightly larger than the print is cut, and placed on a sheet of glass, which has been wiped with a wet sponge. The dry print is then laid on the tissue, both are trimmed to the required size, and are laid in position on the mount. The print is then covered with a piece of clean dry paper and affixed to the mount by pressure of the suitably heated block. The very handy block is sold in 7in. x 5in. size at 7s. 6d., or 10½in. x 8in. at 15s. The tissue is obtainable at 9d. per yard, 18in. wide, or 1s. 6d. per yard, 36in. wide.

CARRYING CASE AND LENS HOOD.—Those who have read Captain Owen Wheeler's recent articles on the advantage of the lens hood in telephoto work, as well as many others who have appreciated the contrivance in ordinary work, will be interested in hearing of an ingenious device which was shown to us a few days ago by Mr. Edgar Clifton, of Messrs. J. H. Dallmeyer, Ltd., 24, Newman Street, Oxford Street, W. This was a wooden carrying case for a large lens, and was so made that, while it answered its nominal purpose perfectly, it served equally well as a hood for the lens. This double purpose it was enabled to perform owing to the provision of a circular aperture (closed at will) which fitted the lens hood. Further, one side of the case was made with a sliding shutter, which could be employed to adjust the shading of the lens to a nicety, and to give a graduated exposure to sky and foreground. These advantages are secured without any addition to the weight of the kit, for the case is made no larger on account of its functions as a hood. Messrs. Dallmeyer are making the hood-cases for any type of lens and telephoto attachment.

AN INTERESTING ENLARGEMENT is to be seen outside the Hicks Theatre in Shaftesbury Avenue, representing a scene from Charles Frohman's production of "Brewster's Millions." The picture is 6 feet by 4 feet in size, and is one of the largest photographs on public exhibition.

## New Materials.

Christmas and New Year Mounts. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

Year by year we find Messrs. Fallowfield to the front with greeting mounts for the Christmas season and the present occasion is evidently to be no exception to its predecessors. The selection of mounts obtainable from the Charing Cross Road firm is a very large and varied one, and allows the most diverse requirements to be satisfied. The plainer and more reserved type of mount is present in a larger proportion than previously, a sign, we hope, that the public is beginning to prefer a really tasteful design to those answering to the description "Christmas-cardy." The latter, it is true, are usually excellent in themselves, but their union with a photographic print is

seldom happy. Messrs. Fallowfield meet the case with cards of both orders, and have produced some most excellent designs, which externally resemble the private greeting card as it has become known of late years, whilst the interior contains a cream folder, which forms an admirable setting for a small bromide or platinotype print. Some cards of this type with Dutch designs are most attractive. However, we can best refer to the 24-page list, wherein will be found fully illustrated particulars of the mounts, together with the details of the special offer (of a set of selected specimens) to dealers and professional photographers. The list is sent free to all on application. The offer is extended only to dealers and professionals.

A SELF-TONING PAPER has been placed on the market by Walter "de" Welford and Co., 61, Mansfield Road, Ilford. The special advantages emphasised by the makers are the speed of printing and the resemblance of the tones to those of gold-toned P.O.P. The paper is sold in 3d., 6d., 1s., and 1s. 6d. packets.

CHRISTMAS MOUNTS AND CALENDARS.—The Crown Photo Manufactory, Rotherham, send us some examples of their Christmas mounts for the coming season. Among the bulk we find a number of brightly printed designs suitable for prints from quarter-plate size downwards. Many people we know prefer plenty of colour and embossed lettering in their festive missives, and photographers catering for them are foolish to offer them anything else. The Crown Factory's selection is excellent in this respect; whilst the "Royal" Calendar, with oval opening for cabinet print, shows that they can also supply mounts of more reserved colouring. The prices in all cases are most moderate.

AUTOCHROME MATERIALS.—"Fallowfield's Courier" for October contains a catalogue of the materials for the Lumière process, which the firm of Fallowfield are preparing to supply specially for the convenience of Autochrome users. These include solutions for the process, which are obtainable singly or in complete sets at 6s. 6d., glass dishes, pneumatic holders, metric graduates, and electric fan for quickly drying the finished Autochromes. Messrs. Fallowfield's circular, obtainable from 146, Charing Cross Road, London, W.C., gives particulars and prices of these items.

CHRISTMAS "CUT-OUT" MOTTOES.—Mr. F. C. Clarkson, Colchester, sends us specimens of some most effective gilt mottoes, which are instantly attached to any mount and convert it into one of specially "Christmassy" character. The gilt of the lettering goes well with almost any colour of mount and print, and gives a very handsome appearance to the whole. The mottoes, which include such phrases

as "Hearty Greetings," "All Good Wishes," or "Remembrances," are supplied, assorted, at 14s. 6d. per 1,000.

**ROTARY CHRISTMAS POSTCARDS.**—The Rotary Photographic Company, New Union Street, E.C., have just issued the sensitised postcards for the Christmas season, bearing suitable mottoes and decoration in the space reserved for communication on the address side. These Rotox and Rotograph cards are attractively produced, and should enjoy a wide sale. A set of similar Rotona cards is also obtainable from a different series of designs.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, OCTOBER 25.

West London Photographic Society. "Autochrome Process." W. G. Cullen.  
Aberdeen Photographic Association. "Toning of Bromide Prints." H. MacLennan.

#### SATURDAY, OCTOBER 26.

Worthing Camera Club. Outing to Shoreham and Southwick.

#### MONDAY, OCTOBER 28.

Bradford Photographic Society. "Yorkshire Minsters." C. B. Howdill, A.R.I.B.A.  
Kidderminster and District Photographic Society. Competition.  
Oldham Equitable Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."

#### TUESDAY, OCTOBER 29.

Birmingham Photographic Society. "Some Schools of Art and their Photographic Imitation." H. Barratt.  
Leeds Photographic Society. "Sea Birds at Home." Riley Fortune.  
Nelson Camera Club. "Rotary 'Carbograph' Paper."  
Bootle Photo. Society. "Photographic Chemicals."

#### WEDNESDAY, OCTOBER 30.

Edinburgh Photographic Society. "First Lesson on Elementary Geometrical Optics." W. J. Macdonald, M.A., F.R.S.E.  
South Suburban Photographic Society. "Time Development." W. F. Slater, F.R.P.S.  
Everton Camera Club. "Naples, Rome, &c." Rev. S. A. Barrett.  
Coventry Photographic Club. Judging No. 1 Summer Competition.  
Croydon Camera Club. "Leto Pigment Paper." F. J. Terry.  
Leeds Camera Club. "My Rambles in Upper Wharfedale." Thos. Ryder.  
North Middlesex Photographic Society. Technical Meeting.  
Chorley Photographic Society. "Rotary 'Carbograph' Paper."

#### THURSDAY, OCTOBER 31.

Chelsea and District Photographic Society. "Portraiture." Harold Baker.  
Queen's Park Amateur Photographic Association. "Lantern Slide Making." David Horn.  
London and Provincial Photographic Association. "Oil Printing." A. W. Green.  
Rugby Photographic Society. Slides of "Tasmania," by Members of the Northern Tasmanian Camera Club.  
Longton and District Photographic Society. "Holland." E. Marks.  
Richmond Camera Club. Amateur Photographer Prize Slides 1907.  
Liverpool Amateur Photographic Association. "The River Mersey from the Moors to the Sea." Dr. John W. Ellis.  
Hull Photographic Society. "The Carbon Printing Process." J. T. Dyson.  
North London Photographic Society. "Mounting and Trimming." Competition.  
Handsworth Photographic Society. "Stand Development." F. Smith.  
Darwen Photographic Association. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Windsor Camera Club. "Photographic Chemicals."  
Nottingham Camera Club. "Ozobrome." H. L. Hopkins.  
Blenheim Club 1. "The Invention and History of Steel Pens." 2. "Gold Pens and their Manufacture." James P. Maglunius.

**KIDDERMINSTER PHOTOGRAPHIC SOCIETY.**—At the annual meeting, held October 14, the following officers were elected:—President, Mr. W. Adam, J.P.; vice-presidents, Messrs. J. A. Batley, R. B. Dawson, H. E. Hadley, and Charles Hughes; hon. treasurer, Mr. G. F. Griffin; hon. secretary, Mr. H. W. West, 12, Shrubbery Street, Kidderminster.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On October 16 the president, Professor H. E. Armstrong, Ph.D., LL.D., F.R.S., gave a lecture of a most interesting nature, on "The Chemistry of Photography," in which he dealt with the theories of the latent image, reversal, and development.

**SUTTON PHOTOGRAPHIC CLUB.**—The report read at the annual meeting, held on October 18, indicated that a notable revival in photographic interest on the part of local amateurs has ensued during the past two years, the effective membership of the club having in that period been almost trebled. Amongst those who have recently joined and especially noteworthy is Mr. Andrew Pringle, who is taking an active interest in the club, not only by giving a demonstration upon Ozobrome on November 15, but also by placing at the

disposal of the members his photographic portrait studio at Banstead, a privilege which should prove of great value to all whose inclination lies in the study of figure photography. Mr. Hector Maclean, F.R.P.S., was reappointed chairman, and Mr. J. W. S. Burmester, F.R.I.B.A., of Fairhome, Grange Road, Sutton, hon. sec. There was a large attendance of members, who were much interested in an account of the work and aims of the Surrey Photographic Survey, which Mr. Maclean explained by the aid of lantern slides.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on Thursday, October 17, 1907, Mr. A. E. Smith in the chair, Mr. Ferry gave a few hints to would-be patentees—a hint was to invent something.

**MORPETH Y.M.C.A. CAMERA CLUB.**—On October 14, 1907, the opening of the winter session commenced with a highly instructive lecture by Mr. Arthur Payne, F.C.S., F.R.P.S., on "In Search of the Picturesque." Mr. Payne showed some examples of autochrome transparencies taken by himself, in regard to which it is stated in the local journal that "It may interest the people of Morpeth to know that they have had an opportunity of witnessing the first exhibition of these colour plates in England, north of Manchester."

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday, October 21, Mr. G. C. Druce delivered his lecture entitled "Animal Sculptures in Church Architecture." The author, who is an ardent archaeologist, has made a special study of ecclesiastical grotesque sculptures, such as are generally found on fonts and misereres, and on the soffits and tympanums of Norman arches, and has endeavoured with very good effect to elucidate their meaning and the story they have to tell.

### CATALOGUES AND TRADE NOTICES.

SEASONABLE lists of enlarging apparatus and Christmas card mounts, have been sent us by Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, E.C., from whom they may be obtained on application by postcard. Messrs. Butcher will supply circular of discounts to bona-fide dealers on application.

**HAUFF PHOTO-HANDBOOK.**—A new edition of the instruction manual for the use of the many Hauff developers has been issued by Messrs. Fuerst Bros., of 17, Philpot Lane, E.C., and will be sent post free on application. Almost all the developing and other chemicals can now be obtained in the convenient "carton" form, but the best formulae for the home preparation of the working solutions are given at some length in the booklet, which also contains particulars of the various brands of Hauff ordinary and orthochromatic plates.

## Commercial & Legal Intelligence.

**ONE MONTH FOR CANVASSING FRAUD.**—In the Stonehaven Sheriff Court last week James Wilson was charged with defrauding a number of farm-servants and others by pretending that he would make them picture postcards at 2s. per dozen, and that on receipt of a deposit, he would send on the photographs by post. The offences were committed in July and August, and the sums received by accused from thirty-one persons ranged from 6d. to 1s. Accused, a man of good appearance, pleaded guilty, and said he was to get a camera, but the man from whom he was to get it said he was doing the work too cheap, and refused to give him the camera. Accused was sentenced to thirty days' imprisonment.

**CANVASSER CHARGED AT BROMLEY.**—At the Bromley Petty Sessions last week Joseph Lemoine (twenty-eight), of 181, Canterbury Road, West Kilburn, was charged with obtaining at Chislehurst sums of money by means of a worthless photographic coupon. Prisoner called called upon a number of domestic servants and represented himself as an agent of a Bond Street firm of photographers who, he said, had opened a shop at Bromley. He was remanded.

### NEW COMPANIES.

**SYNOLOIDS, LTD.**—Registered October 9 by E. B. Gee, 15, Copthall Avenue, E.C. Capital £60,000, in £1 shares. Objects: To adopt an agreement with the S. P. Syndicate, Ltd., to manufacture and deal in the composition known as "Synoloids" and other similar compositions, chemicals, photographic paper, and photographic and scientific appliances. The signatories are:—S. O. Fairn, 85, Grace-

urch Street, E.C., 1 share; L. Lambert, Petworth, Dingwall Road, Croydon, 1 share; S. H. Lee, 85, Gracechurch Street, E.C., 1 share; G. London, Shakespeare House, Lakeside Road, Palmer's Green, 1 share; A. B. Larkins, 33, Philbeach Gardens, S.W., 1 share; A. Hinde, 5, Colwell Road, E. Dulwich, S.E., 1 share; W. Lee, Renthall Avenue, Chiswick, W., 1 share. No initial public issue.

## News and Notes.

**FIRE AT A BRADFORD STUDIO.**—A small outbreak of fire took place Sunday night at the lock-up shop of Mr. Allan Whiteley, photographer, 34, Heaton Road.

**THE R.P.S. DINNER.**—Members are reminded of the date of the Royal Photographic Society's dinner, namely Wednesday next, October 30.

**THE "ENSIGN" ROLL-FILM MONTHLY COMPETITION.**—In the roller competition the three-guinea camera was awarded to Mr. S. Pasco, of 77, Leopold Buildings, Columbia Road, N.E., and several supplementary money prizes to other competitors.

**THE COLOUR OF DYE SOLUTIONS.**—Mr. S. E. Sheppard writes to "Nature":—"It is generally accepted that the colour of dye solutions depends upon the chemical structure of the dye, and colour changes usually attributed to some change in constitution; but certain recent investigations on colloidal solutions show that this argument must be accepted with caution. It is well known that colloidal solutions of the metals are highly coloured. Further, it is recognised that many dyes exist in solution in what, for lack of a better term, is called the colloidal state. Some observations of my own point to the following statement as being true for certain dyes:—The absorption spectrum of the dye in solution may be either (a) a characteristic absorption, consisting of one or more narrow bands and depending on the chemical structure of the dye molecule, or (b) a "resonance" spectrum due to colloidal particles, and much more closely connected with chemical constitution. This spectrum is well defined. The detailed experiments which have led to these conclusions will be communicated in a paper shortly to be published. It is of course of two or two is desirable in explanation of the term "resonance" spectrum. By this is denoted the type of absorption exhibited by colloidal metal solutions, glasses, and certain photographically prepared films (F. Kirschner, "Drude's Annalen," 1904, xiii., 239; Kirschner and R. Zsigmondy, *ibid.*, 1904, xv., 573; K. Schaum and Schloemann, "Zeit. wiss. Phot.," 1907, v., 109). It is probable that all absorption is due to resonance, no doubt, and hence the narrow-band type (a), but in this case the resonators would be the molecules or the contained electrons, whereas in case (b) the resonance is due to larger aggregates is the cause of the absorption. The investigation must be continued, but a striking case was found in one of the pinacols, a class of dyes recently introduced as photographic sensitizers. This dye gives in aqueous solution a flattish, ill-defined absorption, the solution showing all the characteristics of a colloidal solution. In alcohol and organic solvents the absorption was of a narrow-band type, entirely different, and this spectrum was also obtained by dissolving the aqueous solution to boiling point. The behaviour was analogous to that of starch, which gives crystalloid solutions on boiling point.

**FIXING.**—Messrs. John J. Griffin and Sons, Ltd., write from Kingsbury, W.C.:—"For some time past we have been enforcing the desirability of using acid fixing bath with our "Velox" paper. It is not generally known that the use of an acid hypo bath for "Velox" paper, or indeed any gaslight paper, is absolutely essential. The worker wishes to keep clear of pitfalls. If a plain hypo bath is used it is almost impossible to prevent stains and blisters, whereas an acid hypo bath properly compounded these would not occur. We believe nine-tenths of the failures with gaslight papers are caused by using an improper fixing bath. For some time past we have been using the ingredients for making this special fixing bath in a tin, and the same at 6d. Lately we have found it desirable to issue this bath under a distinctive name, as many photographers, when asking for an acid hypo, have obtained something else. We have therefore

called our acid-fixing preparation "Acifix." It is made up according to our formula, and will not throw a deposit of sulphur.

**STOLEN APPARATUS.**—The following notice has been issued by the Hove police:—"Stolen in the above borough, on the 8th inst., a No. 4a folding pocket Kodak with Goerz "Dagor" lens, No. 2/212360, by a man giving the name of Walker, aged about 27 years, height 5 feet 11 inches, pale complexion, fair, clean shaven, small scar on bridge of nose, widening of nose just below the eyebrows, partially cutting off the eyes when viewed full face, medium build. Information to Chief Constable, Hove, Sussex.

**CROYDON CAMERA CLUB.**—The ninth annual exhibition will be held in the Art Galleries, Park Lane, Croydon, from November 20 to 27 inclusive. The judges will be Messrs. Furley Lewis, Harold Baker, and B. Gay Wilkinson. In four of the six open classes the awards will be a silver cup, bronze plaque, and hon. mention. In Class D, which is devoted exclusively to colour work, the awards will be a silver plaque and hon. mention; and a bronze plaque is offered in Class F to all amateurs residing in Croydon and district, who are neither past nor present members of any photographic society. A silver gilt plaque will also be awarded to the best picture in the exhibition. Entries close November 6, and entry forms and full particulars may now be obtained from the exhibition secretary, Mr. H. T. Dodsworth, Enmore House, Woodside Green, South Norwood. Exhibits at the Hackney Photographic Society's exhibition may be transferred free of cost to Croydon, if instructions to this effect are given on the entry forms of both societies.

**INSTRUCTION IN THE AUTOCHROME PROCESS.**—The "Amateur Photographer" says of the book of instructions issued by Messrs. Houghtons Limited at 2d.:—"Instructions for the new Autochrome process are now obtainable at the small cost of twopence, in a booklet by two thoroughly competent and successful early workers of the method, Mr. George E. Brown and Mr. C. Welborne Piper. Messrs. Houghtons Limited are agents for the sale of this timely production." "Focus" writes:—"It is a complete manual on the process, giving full and lucid instructions for the manipulation of Autochrome plates, and should prove extremely useful to the many photographers now experimenting in direct colour work. Some useful hints on the prevention of frilling, etc., are included, and the section explaining the influence of over and under-exposure is specially valuable. . . . We would recommend dealers to waste no time, but make prompt application for a supply, as no doubt this little book will be very popular."

**PHOTOGRAPHS BY TELEPHONE.**—Much attention is now paid in Germany (writes the United States Consul at Chemnitz) to the remarkable measure of success which has attended the installation of Professor Korn's invention for the transmission by wire of photographic reproductions over long distances. His latest experiments show that nearly as satisfactory results are secured by making use of ordinary telephone wires as on lines specially constructed for the purpose. The only difficulty encountered on telephone wires results from calls on adjoining wires. These cause the formation of zigzag lines on the reproduced picture at the receiving station; but they are easily corrected by retouching. Alterations in current intensity by ringing on or ringing off, as well as during conversations over adjoining wires, are without effect. It is further shown that the wire employed for photographic reproduction can simultaneously be utilised for telephonic conversation. The first journal to utilise the new invention is the "Copenhagen Daily Politiken," which has ordered a complete installation for telephonic and telephotographic communication with its Berlin offices.

**TRAILL TAYLOR LECTURE.**—The tenth annual memorial lecture was delivered at the New Gallery on Tuesday last, October 22, by Mr. S. D. Chalmers, M.A., head of the optical department of the Northampton Institute. The subject, "Aberrations in Photographic Lenses," was necessarily of a very technical character, but proved exceedingly interesting from the fact of the "aberrations" being treated from an unusual point of view. In the discussion which followed the lecture Messrs. Conrad and Horace Beck took part, and there seemed a general consensus of opinion that the Petzval condition need not necessarily be fulfilled in photographic lenses, though at certain times and under certain conditions it may prove useful. The proceedings closed with a hearty vote of thanks and presentation of the medal to Mr. Chalmers.

### THE NEW COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—There is one point which has occurred to me in connection with this very ingenious process, and one which I have not seen mentioned in any articles which have been written about it, and that is, whether the colours are all permanent. Presumably Messrs. Lumière have satisfied themselves on this point, because, should it prove otherwise, the pictures would in time present a rather remarkable appearance, and the colours anything but true to nature.

Of course, the process is but a variant on the three-colour process, and possibly the same colours are used to dye the starch grains as are used to dye the gelatine films used for that process. If so, there may not be much doubt, unless it may be that starch acts differently to gelatine.
